member is to be appointed)

### OFFICERS OF THE SECTIONS FOR 1940

ELECTED BY THE SECTIONS

(The street addresses may be obtained from the Directory of Fellows)

#### SECTION OF MEDICINE

*Chairman* C. M. Jones Boston *secretary* E. C. Miller Worcester

#### SECTION OF SURGERY

*Chairman* R. H. Smithwick Chestnut Hill and Boston *secretary* B. C. Wheeler Worcester

#### SECTION OF PEDIATRICS

*Chairman* C. F. McWhann Boston *secretary* J. M. Baty Belmont and Boston

#### SECTION OF OBSTETRICS AND GYNECOLOGY

*Chairman* R. J. Heffernan Brookline *vice-chairman* M. F. Eade and Boston *secretary* R. S. Titus Boston

#### SECTION OF RADIOLOGY AND PHYSIOTHERAPY

*Chairman* E. C. Vogt Boston *secretary* C. L. Payzant, Boston

#### SECTION OF DERMATOLOGY AND SYPHILIGOLOGY

*Chairman* C. Guy Lane, Belmont and Boston *secretary* J. G. Dow and Boston

## OFFICERS OF THE DISTRICT MEDICAL SOCIETIES

ELECTED BY THE DISTRICT MEDICAL SOCIETIES AT THEIR ANNUAL MEETINGS BETWEEN APRIL 15 AND MAY 15 1939

(The street addresses may be obtained from the Directory of Fellows)

BARNSTABLE — *President* C. H. Keene, Chatham *vice president* O. S. Simpson  
Falmouth *secretary* D. E. Higgins Cotuit *treasurer* H. B. Hart Yarmouthport  
Liberal E. E. Hawes Hyannis

BIRMINGHAM — *President* H. J. Downey Pittsfield *vice president* J. W. Bunde,  
North Adams *secretary* G. S. Reynolds Pittsfield *treasurer* C. T. Leslie Pittsfield

BOSTON NORTH — *President* R. M. Chambers Taunton *vice president* I. A. Reese Attleboro *secretary* W. H. Swift Taunton *treasurer* J. V. Chaugay Taunton

BOSTON SOUTH — *President* Thomas Almy Fall River *vice president* H. E. Perry New Bedford *secretary* and *treasurer* A. H. Stearns New Bedford.

FAIRBANKS — *President* H. F. Dearborn Lawrence *vice president* R. C. Norris Methuen *secretary* H. R. Kurth, Methuen *treasurer* G. L. P. Hudson, Haverhill

FAIRBANKS SOUTH — *President* Horace Palmer Salem *vice president* B. B. Mansfield  
Lowell *secretary* J. R. Shuchinsky Salem *treasurer* Andrew Nelson III Danvers

FRANKLIN — *President* F. J. Edmund Greenfield *vice president* A. H. Wright Northfield *secretary* and *treasurer* C. J. Moline Southfield

HAMPSHIRE — *President* F. H. H. Smith Haverhill *vice president* I. B. Brown  
Haverhill *secretary* and *treasurer* W. C. Barnes Southfield

HAMPSHIRE SOUTH — *President* J. A. Murphy Fitchburg *vice president* A. P. Simey  
Chesham *secretary* and *treasurer* I. D. Co. Northampton *treasurer* A. H. O'Keefe Northampton

MIDDLESEX EAST — *President* C. R. Baisley Reading *vice president* Murphy Melrose *secretary* K. L. MacLachlan Melrose *treasurer* R. Wakefield Woburn J. M. Wilcox Woburn

MIDDLESEX NORTH — *President* F. L. Gage, Lowell *vice president* Lowell *secretary* E. A. Payne Lowell *treasurer* M. D. Bryant, Lowell P. J. Meehan Tewksbury

MIDDLESEX SOUTH — *President* Dwight O'Hara Waltham *vice president* Day Cambridge *secretary* A. A. Levi Cambridge *treasurer* E. Newton Woburn E. J. O'Brien Brighton

NORFOLK — *President* C. I. Kickham Brookline *vice president* F. Milton *secretary* F. S. Cruickshank Brookline *treasurer* Frederick Plunk

NORFOLK SOUTH — *President* D. B. Pearson, Quincy *vice president* Sergeant Quincy *secretary* P. L. Cook Quincy *treasurer* F. W. C. Brook L. R. Cook Quincy

PLYMOUTH — *President* A. W. Carr Bridgewater *vice president* S. Brockton *secretary* H. C. Peed, Whitman *treasurer* A. M. Ch. Whitman J. H. Weller State Farm

SUFFOLK — *President* Reginald Fitz, Boston *vice president* A. Boston *secretary* M. H. Clifford, Boston *treasurer* W. T. S. Thore

WORCESTER — *President* J. C. Quinn Worcester *vice president* Worcester *secretary* G. C. Tully Worcester *treasurer* E. P. Ditt  
Worcester *secretary* A. C. Gerbail Worcester

WORCESTER NORTH — *President* E. P. Sweeney Leominster  
H. C. Act Gardner *secretary* E. A. Adams Fitchburg *treasurer* S. J. Fitchburg

## THE TEACHING OF THE MEDICOSOCIAL ASPECTS OF CASES\*

GEORGE P. REYNOLDS, M.D.†

BOSTON

THE older generation of today remember their early family doctor for his kindly manner, cheerfulness, understanding, sympathy and practical advice. They now realize that his knowledge of medicine was inadequate as judged by modern standards, but in retrospect at least, this seems relatively unimportant to them. His medical education was chiefly along practical lines, and if he was one of the more venerable men of that day, it had been acquired aside from the study of anatomy, largely if not entirely through daily association with some older physician, in his buggy making visits, and in the hospital.

The age of Bernard, Virchow, Pasteur and Lister saw the dawn of modern research in clinical medicine, and the beginnings of applied science in its teaching. As a result, pathology, bacteriology, physiology and biological chemistry have been added to the older study of anatomy, and now form the basis of medical education. If considered in the light of advancement of knowledge this change has been altogether desirable, and its value has been unquestionably shown in new and improved methods of diagnosis, treatment and prevention of disease.

But the *practice* of medicine includes much more than an attempt to control disease by scientific methods. Eighty years ago James Jackson<sup>1</sup> in his *Letters to a Young Physician*, said

From this day you must realize more and more the difference between the study of the sciences and the application of them to the business of life,—to the practice of your art. First, because many principles, on which we act, are not established on certain ground and therefore they must be followed with great caution and constant watchfulness. Second, because there are few principles which are universal in their application.

Later in the same letter he compares the art of medicine to that of navigation.

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard Medical School.

\*Instructor in medicine, Harvard Medical School; junior visiting physician, Boston City Hospital.

In the practice of each of these arts we avail ourselves of the laws of nature to produce certain results. The seaman places his ship upon the waters, and avails himself of the winds to propel it. These winds are uncertain, they are not, in any way, subject to his control, so that he cannot be sure as to the duration, the comfort, or even the safety of the voyage, he cannot furnish a pupil with positive rules by which to conduct his bark across the Atlantic. The Captain must have regard to the qualities of his ship, the strength of his crew, and to the constantly varying circumstances of the weather. The complexity here is much less than attending the treatment of a disease, for in this we have to do with a living being.

Medicine is not, and never will be, an "exact science" which can be practiced by the precise methods of reasoning and deduction of the mathematician, the chemist or the physicist. The reaction, both mental and physical, of the human being to any external or internal factor is an ever-present variable which prevents the accurate and unfailing relation between cause and effect that characterizes the work of the true scientist. The engineer who wishes to construct a bridge that is to support a given weight can, through his knowledge of the strength of its component parts, prophesy with considerable accuracy the strength of the whole structure. The chemist can foretell the reaction that must result when two compounds are brought together under given conditions. But where living organisms are involved individual variation precludes any such exactitude, and in medicine the innumerable social, economic, psychiatric and physical elements of each situation make this variation an ever-changing factor in the reaction of the human being at various times in his life and even during the course of a brief illness.

Henderson,<sup>2</sup> in his most absorbing interpretation of Pareto's *General Sociology* points out that many of the subjects taught in our universities may be divided into two classes: first, history, literature, economics, sociology, law, politics, theology, education, and so forth; second, logic, mathematics, physics, biology and other natural sciences gram-

mar, harmony, and so forth. He states that when the authorities on the latter group of studies disagree it is "most often at the frontiers of knowledge, where growth is taking place, and in the long run a debated question is ordinarily settled by observation, experiment, or some other method that all accept"—in other words, by the methods applicable to any true science. This, Henderson tells us, is not in general true of subjects of the first class, because "all of the subjects of the first class do involve, and no one of the subjects of second class does involve, the study of the interrelations of two or more persons."

If we attempt to place the study of medicine in one of these classes we at once see that it must be divided into its component parts. The basic sciences such as anatomy, physiology, chemistry and so forth unquestionably fall into the second group, but the *care of the patient* indubitably belongs in the first class, for one cannot treat the patient without regard to his social environment, and two or more people are involved.

A tendency to focus the emphasis in the modern teaching of medicine on the physical and laboratory approach to diagnosis, treatment and prevention of disease is liable to obscure the importance of those methods and qualities which enabled the old-fashioned family doctor not only to bring happiness, solace and mental tranquility to his patients, but also, by his knowledge of them as individuals and as human beings, to discover and evaluate factors bearing a significant relation to their illnesses which would not have been revealed by the most complete modern laboratory studies or by the usual routine history and physical examination of today.

The clinical aspects of medicine are now taught principally in the public wards and outpatient departments of hospitals. This is necessarily so, and from the point of view of the study of disease the public hospital with its wealth of available clinical material is the best place for such teaching. But the difficulty is that in these surroundings the patient is likely to be stripped of his personality, his human relationships and the complexities of his own particular life and environment. The student, the intern and even the instructor tend to speak of him as a "case of gastric ulcer," for example, and to forget that he is a human being. As a result, they fail properly to investigate and consider the economic, occupational social and psychological problems that he is facing, and that may have a direct or indirect bearing on the etiology and treatment of his illness.

Moreover, there is still a tendency to speak of all symptoms as either *functional* or *organic* and to

base their treatment upon this arbitrary method of classification. It is generally recognized that symptoms arise when some organ has a lesion and therefore functions abnormally. It seems to be realized by but few physicians that environmental factors often cause dysfunction of an organ or organs, and that dysfunction may result in a lesion. Yet there is much evidence that anxiety and nervousness may lead to gastric hyperacidity and eventually to gastric ulcer,<sup>3</sup> that exacerbations of arthritis frequently follow prolonged periods of mental or physical overactivity<sup>4</sup> and that arterial hypertension is found with significant frequency in the tense high-pressure type of individual.<sup>5</sup> Cobb<sup>3</sup> points out that certain diseases, such as paralysis agitans, formerly classified as functional are now known to show definite pathologic (cellular) changes, and are therefore organic. He prophesies that new or improved methods of investigation will demonstrate that other so-called functional ailments have pathologic changes and will be accepted as organic. These terms, therefore, are but arbitrary divisions of an indivisible field and should be avoided. Rather than attempt such a differentiation we should devote our attention to a consideration of the etiologic relation of environmental factors, symptomatology and physical and laboratory evidence of disordered function of the body as an organism, and realize that anything which happens to that organism is organic.

Frequently in a hospital the study of the environmental factors of the "case" is delegated to the social service department, but all too often it is entirely disregarded. Moreover, the function of the social worker is to act as a consultant who considers one particular portion of the patient's problem and renders an opinion on it to the physician in charge. One would scarcely expect the roentgenologist to make his studies of a patient without reporting his results to the physician, much less would one expect him to institute such treatment as seemed to him advisable without consulting the physician. Yet this is often the attitude taken toward the social worker. A summary of the social-service investigation and the recommendations resulting from it should be incorporated in the patient's record as routinely as are consultations from medical specialists such as the aurist, the roentgenologist and the gynecologist. It is in this way only that the various aspects of the patient's problem can be properly integrated by the physician in charge, yet it is seldom done.

The result of this basic defect in the hospital routine—this lack of proper liaison between the physician and the social worker—is further to hide from the student and the house officer the

importance of considering the social aspects of each case before drawing final conclusions as to its correct diagnosis and proper management. The individual whose medical experience has been confined to the study and care of the patients within the walls of a hospital, be he student, intern or visiting physician, is prone to look on the work of the social-service department largely as a charitable endeavor to better the lot of poor and uneducated patients. He thinks of social problems as being almost exclusively the result of financial distress. This is of course entirely erroneous, as similar and often more complex social problems arise in cases among the well-to-do. Aside from the assistance which the social workers give in arranging for the disposal of patients with chronic or incurable diseases, he sees very little correlation between their activities and his own. The student is not interested in the medicosocial aspects of the cases, chiefly because he does not appreciate their important relation to the etiology of symptoms, the practice of medicine and the prevention of illness.

The foregoing criticisms should not be construed as implying that attempts to teach the medicosocial approach to medical problems have not been made in the past, or are not included in the present curriculums of many medical schools. Edsall in 1912 introduced such teaching of students at the Massachusetts General Hospital.<sup>6</sup> Minot<sup>7, 8</sup> has stressed its value for many years. Many psychiatrists have been emphasizing its importance as a therapeutic procedure for a quarter of a century. And in the last few years instructors at various medical schools and in many fields of medical education—internists, psychiatrists, pediatricians, surgeons, teachers of preventive medicine, public health, and hygiene and social workers—have given lectures or special courses to medical students on this aspect of medicine. But despite these attempts of individuals, the fact remains that the social approach to the study of medical cases has received insufficient emphasis as a whole in the education of medical students, and has been totally neglected by many clinical instructors. The need is to permeate the entire curriculum with such teaching, rather than to confine it to any single department or teacher.

#### OBJECTIVES

It would therefore seem most desirable to bring about a change in the usual approach to the clinical teaching of medicine. We should attempt to develop in our students a greater interest in the patient as a human being, and should therefore avoid discussing his problems largely as phenomena of diseased organs or disordered function.

We should adopt a more humane rather than a purely material attitude toward the problem of the individual. We should return to a greater emphasis on the *health* and *happiness* of the patient as the primary aim of medical practice, but not at the expense of minimizing the importance of the control or cure of disease. In all contacts with students we should keep in mind the following objectives to develop in their minds a consciousness of the importance of the social aspects of medicine to the practice of their art, to bring to them a realization of their responsibilities as physicians, not only to the patient, but to his family, the community and humanity, to teach them how to elicit and evaluate in scientific fashion the social factors of the individual case, and to demonstrate how to construct a plan of treatment that is socially as well as medically adequate and applicable to the peculiar circumstances of the individual patient.

#### *Importance of Social Aspects*

The value of social study in diagnosis, the essential part that it plays in determining the exact treatment of the case and its role in the prevention of disease and of psychological maladjustments, both for the patient and for his associates in life, must be demonstrated to the student. He must be made to see clearly that this is an integral part of medicine itself, not merely an allied field of social endeavor. He must be reminded of the historical fact that social-service departments were created in public hospitals because this aspect of the cases of indigent patients was of necessity being neglected by busy physicians, but that these departments represent merely a dissemination of the function of the physician. The study and evaluation of the social component of each medical problem is, moreover, a duty which the physician has to assume unaided in dealing with his private patients. If the student can be made to realize this fully, he will be much more willing to learn the technic of social study and of its application.

#### *Realization of Responsibilities*

In discussions of the social aspects of medicine with students one is frequently asked such questions as these: Is it the physician's duty to go into family affairs so remotely connected with the patient's disease?<sup>1</sup> Does not his responsibility end with the treatment of that disease, or at most of the patient himself?<sup>2</sup> Does not this belong to the field of preventive medicine, or psychiatry, or a social-welfare agency?<sup>3</sup> In order to answer these questions satisfactorily it is necessary to give the student a panoramic view of the whole field of

medicine At one end of the picture we have the chemist, the bacteriologist and the physiologist, studying problems concerning disease, and working entirely in the laboratory Next comes the trained clinical investigator Near him stands the public-health officer, striving by experimental and practical methods to prevent and control disease in the community In the middle we have the more strictly limited aspects of practice, the specialists who attack the patient's problem from but one point of view They diagnose and treat ailments in their own particular field They have methods and weapons especially adapted to their use—the surgeon's knife, the cardiologist's stethoscope and electrocardiograph, the laryngologist's head-mirror and bronchoscope, and so forth At the other end of the panorama we have the psychoanalyst, who deals exclusively with the abnormalities of intellect and the emotions—the field so stupidly and incorrectly described as functional disorders His work, at the extreme edge of the picture, touches that of the father confessor and spiritual adviser, the philosopher and the sociologist And to him a complete knowledge of the social environment—in the broadest sense of the word—of his patient is essential

But the picture is not divided into clear-cut sections or groups The work of each touches that of all the others Certain of the methods and discoveries of the pure scientist are applicable to each of the specialties Every human being has his own psychological peculiarities And throughout the whole panorama we have the internist, or to use the older and more descriptive term, the general practitioner His functions are many He serves as liaison officer between all the other groups He is the jack-of-all-trades who does the jobs that do not fall directly into the other fields He is himself a specialist in medical ailments He often acts as a clearing house by directing patients to the specialists appropriate to their needs His work carries him from one end of the panorama to the other, and to fulfill his function he must be acquainted with and occasionally take an active role in the work of each group Moreover, every one of these individuals is dealing with human beings, each with his own peculiar life, environment and extramedical problems If we accept the hypothesis that the practice of medicine involves the study of the interrelations of two or more persons, we must admit that each of these workers must consider the social aspects of every case that he cares for The cardiologist has not helped his patient when he advises a sedentary life or "light work" to an individual who has a family to support and whose only means of livelihood is mov-

ing furniture If, through his knowledge of the patient's talents, through the aid of social agencies or by any other means the cardiologist finds or suggests some employment for the patient that is compatible with his physical limitations, he has more fully performed his function as a physician In so doing he has not only aided the patient, but also his family and the community, which would otherwise have been obliged to care for them all Such considerations as these, with simple illustrations from actual cases, should enable us to convince the student of the scope of his responsibility as a physician and his duty to society as well as to the individual He will then see that it is a part of the duty of every physician, whether he be a specialist or not, to act at times as a public-health officer, at others as a psychiatrist, and to try to prevent disease as well as to cure it And he will realize that he must often become involved in social situations apparently remote from his patient's disease in order to assist in the control or cure of that disease

### *The Elicitation and Evaluation of Social Factors*

The term "environment" includes, in its social sense, not only geographical surroundings but social relations,—contacts with other individuals—indeed all the factors which have an influence on the individual's reaction to life Every human being has his own peculiar environment, therefore every medical case has its social aspects The evaluation of the social data in relation to the patient's ailments depends first of all on the physician's ability to elicit the story The student must be made to realize that the usual brief summary of the social, marital, economic and occupational history found in hospital records is entirely inadequate A knowledge of the patient's ambitions, hobbies and interests, of his daily contacts and his reactions to them, should be acquired, and his moods, his thinking processes, his understanding of his illness and his ability to adjust to the handicaps which it imposes should be evaluated The physician must know, in short, the intimate details of the patient's personality and his environment, and in order to acquire this knowledge he must gain the patient's confidence The experienced physician or social worker seldom expects to gain all this data at the first visit, and if the patient is acutely ill little or none of it can be elicited from him Much of the history may be learned from interviews with friends, business associates and members of the family Indeed, even brief conversations with his daily companions may reveal in these individuals themselves factors deeply affecting the patient's psychological environment The wife, in telling you of her

husband's symptoms, may reveal traits of her character that are pertinent to the situation. The manner in which his partner inquires about him over the telephone, or simply the dissolute appearance of the son whom you meet on the stairs or glimpse at a late breakfast, may give significant clues to problems and complexities in the patient's life.

In this study of the environment one is greatly handicapped if the patient is seen only in the physician's office or the hospital. Often, in private practice, it is desirable to seek deliberately an excuse to see the patient in his home surroundings, or to have an interview with him in his business environment. Although this is seldom possible to arrange for the student, its significance should be impressed upon him.

The value of these factors in the treatment of a sick person cannot be overemphasized. I<sup>9</sup> alluded to the importance of their consideration in a communication a few years ago, and much further thought on the subject has only served to strengthen my convictions. In this age of mechanization and laboratory investigation, with its ever-increasing number of tests and diagnostic procedures, we are all too prone to forget the importance of treating the patient as a whole man, as "he" or "she" rather than as a "case."

The mere acquiring of social data is not sufficient. Their evaluation in relation to the patient's illness requires the ability to see his problems from his point of view, rather than to judge of their significance by our own standards. The workingman's tenement may seem squalid to us, but entirely adequate to him. An illness which to us is trivial may fill him with terror and desperation. On the other hand, apparent success in any field of endeavor may be far short of the patient's aims, or his ambition may lie in an entirely different direction. For example

In the case of the youthful president of a large and prosperous business concern, it was learned that he had always wanted to go into a profession, but that he had been forced by family considerations to go into the business in conducting which his father, the former president, had committed a crime and became a fugitive from justice. There was friction and jealousy among his board of directors, all of whom were older men who resented his succeeding his father. As a result, the patient had developed a deep sense of frustration and failure. This, on proper evaluation, proved to be the sole cause of the symptoms which at first seemed to point strongly to the diagnosis of peptic ulcer.

In order to decide what role such factors play in any case we must gain a thorough insight into the patient's reaction to his environment, and not be misled by a few superficial evidences of social, marital or economic prosperity. The eliciting of

the social history demands tact, patience and keen perception. Its evaluation requires imagination, experience and the ability to see the problems through the patient's eyes.

### *Development of a Socially and Medically Adequate Plan of Treatment*

The weakest point in the program of treatment in a public hospital usually develops at the time of the patient's discharge. Prior to then he has been the subject of detailed study and care by experienced clinicians, able clinical investigators and enthusiastic and watchful interns. He has had the benefit of the combined knowledge of many members of the staff of the hospital. But the planning of aftercare and his instruction in it are usually left largely or entirely to a house officer whose medical experience has been limited to hospital work, who has had no opportunity to study the problems of convalescence in the home and whose supervision of patients while at work has been confined to a few months in the outpatient department.

The first step in the planning of aftercare is to give the patient or his family as thorough as possible an understanding of his illness, its resulting limitations, their probable duration and their implications in regard to his future life and activity. Obviously the psychological effect of such information must be considered, and it is frequently advisable to pass much of this information on to relatives rather than to the patient. It must be remembered, however, that the patient is the one who must make the adjustment and carry out the instructions, and that therefore he must be given as complete an understanding of his situation and the reasons for each limitation as is consistent with his psychological welfare and happiness.

An intelligent police officer who had been on the ward for many weeks slowly recuperating from a severe coronary thrombosis was about to be discharged, the intern reported that the patient had been given a thorough understanding of the nature of his condition, its implications and limitations, that he had already arranged to be retired from the police force and that his future course of convalescence had been carefully planned for him. Partly for the purpose of demonstrating to the students the details of such planning and partly to elicit personally the patient's reaction to his limitations, the visiting physician asked the patient what he was going to do when he went home that afternoon. "Put the wife and kids in the back of the car and start for California. We ought to make two hundred miles before dark," was the surprising answer. Further questioning revealed a complete lack of understanding of the situation not only by the patient but by the intern as well. The latter, apparently assuming that all policemen are patrolmen, had informed the patient that his work was not compatible with the degree of cardiac damage he had suffered, that he should resign from the force and spend the next few months sitting

around outdoors' The patient, having been a sergeant attached to police headquarters, whose duties were almost entirely clerical, had interpreted this as implying that his sedentary life had been the cause of his illness, and that an outdoor life was advisable. To his mind driving an automobile eight or ten hours a day was a pleasant way of "sitting around outdoors, and he had been busily mapping out a tour that would include every state in the Union. With proper social planning his retirement was changed to a temporary leave of absence, his convalescence was completed at home, and he was then able to return to his previous duties with only slight modifications. In this case the intern, through lack of attention to detail, had entirely failed to acquire for himself, or to give the patient, an understanding of the medicosocial situation, and had thus allowed the patient to develop for himself a most undesirable program of aftercare. The revelation of his failure did much to make the house officer appreciate the importance of careful instruction to patients on discharge.

Another point to be remembered in drawing up a plan of treatment is that it is often important to consider the health and happiness of the patient rather than the prolongation of his life

An elderly lawyer with hypertension and some anginal pain was told by an enthusiastic young physician that he must give up all use of tobacco and alcohol, retire from business and stop playing golf. The patient, feeling that these orders forbade the very things that made life worth living, decided after mature deliberation to defy them all. He smoked and drank distinctly more than had been his habit, worked harder and played harder. The result, as may be supposed, was severe and frequent attacks of pain, which he tried unsuccessfully to disregard. After a few weeks he consulted another physician, who, without knowing of the previous advice, counseled moderation in all things. 'Continue to have your cigar after lunch and two in the evening, but cut down on the cigarettes that you really don't care for anyway. A highball in the evening will do no harm, but avoid cocktails when you can. At sixty-eight you should try to delegate as much work to others as possible, and take at least two afternoons away from the office each week. If you will give up the next six weeks to getting rested, on a definite regime, you will be able to carry on a fairly normal life afterward. There is only one rule which you must promise to obey. Whenever you have an attack of pain stop whatever you are doing and sit down, even if it is on a curbstone, until the pain goes away. You are going to be able to enjoy a good many more years if you will take reasonable care of yourself. The patient joyfully accepted this regime, and today at the age of eighty-four is alive, happy and in reasonably good health.

Finally, it is often more important for the plan of treatment to be practical for the patient and his family, and compatible with his financial and occupational resources, than for it to be the ideal therapy for his disease. The office worker may be unable or unwilling to take milk and cream every hour, but can perhaps arrange for a bland diet, regular meal hours and repeated brief periods of relaxation, which are often quite as effective in the treatment of peptic ulcer. A wage-earner with diabetes may not be able to give up

time to enter a hospital for regulation of his disease, or be willing or able to weigh his food, but such individuals can, more frequently than is often realized, be treated successfully while at work, and can learn to estimate the composition of food intake with sufficient accuracy to permit satisfactory insulin therapy.

## METHODS

A study of the methods of teaching of the social component of medicine that have been employed, or are now in use throughout this country, reveals wide variations in both the character of the teaching personnel and the approach to the subject. The instruction is conducted by many different departments of the various medical schools, and in some by social workers without the aid of physicians. It is attempted variously by lectures, medicosocial ward rounds, case studies, case presentations, conferences and in some instances visits to the home. It seems obvious that one should not attempt to decide which of these means to a common end is the best. Each has its own advantages, and in all probability all are largely successful in accomplishing their purpose. The type of individual available for such teaching in each medical school and hospital will govern the selection of instructors, and the method of teaching will depend on the peculiar abilities of the individual and the exigencies of the situation at that particular medical center. The essential thing is to present to the student the medical approach to his cases in the most effective way that is possible.

Much deliberation on the various methods employed in other clinics, together with personal experiences at the Harvard Medical School unit of the Boston City Hospital, has, however, led to the formation of certain general conclusions.

That the teaching of the medicosocial aspects of cases is most effective if conducted by a physician rather than by a social worker alone.

That the function of the social worker in such teaching should be subsidiary to, though in close association with, that of the clinician.

That the case method of presentation, whether on ward rounds, in outpatient departments or in conference, is more suited to this teaching than didactic lectures alone.

That the subject should not be introduced as a separate entity, but in close correlation with the purely medical aspects of a disease or a case.

That the ultimate aim is to have such teaching permeate the whole medical curriculum, in all discussions with students that deal with diagnosis, prognosis and the treatment and prevention of illness.

## SUMMARY

The need for the teaching of the medicosocial aspects of cases is emphasized, the objectives of such teaching are outlined and discussed, and cer-

tain general conclusions as to the methods of teaching are presented

## THYROID SURGERY AT A LARGE MUNICIPAL HOSPITAL\*

ROBERT C COCHRANE, M.D.†

BOSTON

THIS report covers a series of 559 consecutive cases of thyroid disease treated surgically at the Boston City Hospital from 1925 to 1937, inclusive. Many patients entering a municipal hospital are at the end of their physical and economic rope. Because of this, and because of administrative problems not encountered in private institutions, special measures must be adopted in order to obtain satisfactory results. During the years covered by this series, no patient has been denied his chance for health by operation.

Prior to 1925 only occasional thyroid operations were done in the hospital. Because of unstandardized treatment many of the results were unsatisfactory, and the belief arose that thyroid surgery in this type of hospital was unsafe. Encouraged by two of our medical colleagues, Dr. Burton E. Hamilton and Dr. W. Richard Ohler, we began an attempt to organize thyroid surgery in the hospital.

In the beginning, thyroid cases were not assigned to me, but were obtained because of a demonstrated interest in them. The early cases were mostly poor risks and the mortality was high. Iodine had not been long in use, and frequent multiple-stage operations were necessary. Many patients refused operation. The interns were entirely inexperienced in the operative technic and postoperative care of thyroid patients. Patients were in thirty-bed wards and there was no way of isolating them. At this period the hospital itself was in the process of reconstruction. Wards were being torn down and new buildings being erected. The machine-gun rattle of pneumatic riveters did not make for a satisfactory convalescence. An anesthesia service did not exist. Each new anesthetist had to acquire experience with thyroid patients, and the apparatus then in use was difficult to manage.

After a time we were able to demonstrate the

wisdom of assigning these patients to one surgeon. The staff generously did so on the basis of an annual assignment and subsequently made this permanent. The number of patients has steadily increased. The assignment of cases to one surgical service has meant a sacrifice by the other members of the staff, but it has benefited the patients. If the cases were rotated, in a staff of forty members no one surgeon could acquire enough experience to justify his doing thyroid operations. The new system has also made possible a thorough training of one group of interns, and operating is now being done by other surgeons on the service.

In 1932 a Thyroid Clinic was established in the Out-Patient Department. This is a diagnostic and follow-up clinic open one day a week. Its personnel includes both physicians and surgeons. It has been a very valuable part of the organization. In 1933 the Trustees made it possible to isolate female patients in semi-private rooms. Men had to be cared for in a large ward until 1938, when the opening of the new Dowling Building did away with this difficulty.

#### PREOPERATIVE CARE

Very few thyroid patients are admitted directly to the Second Surgical Service. Admissions to the hospital are either from the Out-Patient Department, in which case they have been studied in the Thyroid Clinic, or from the patient's family physician. Only non-toxic patients are referred directly from the Thyroid Clinic to the surgical service. All other thyroid patients are admitted to a medical ward for preliminary study, and soon after admission the surgeon is requested to see the patient in consultation. Meantime the patient is at rest, and study of the metabolic rate and blood chemistry is being done and existing complications, if any, are being treated. This preliminary survey by the surgeon is extremely valuable. It enables him to estimate more correctly the degree of toxicity than would be possible after the admin-

\*Read at the annual meeting of the New England Surgical Society, Boston, October 1, 1938.

†Assistant professor of surgery, Harvard Medical School; surgeon-in-chief, Second Surgical Service, Boston City Hospital.

istration of iodine Unfortunately, a large percentage of patients are given iodine at home regardless of the type of pathologic lesion, and this not only makes the diagnosis more difficult but occasionally does positive harm In 1 patient with a non-toxic adenoma active toxicity was induced by the taking of iodine

Our custom has been to give iodine to all toxic patients Those with hyperplasia are benefited Certain of the nodular group apparently do not obtain a remission, but in our experience none have been harmed The patients are seen again by the surgeon after medical treatment, and if ready for operation they are then transferred to the surgical service In uncomplicated cases, patients usually obtain maximum remission following iodine therapy in seven to ten days

#### PRELIMINARY MEDICATION

The night before operation the patient may be apprehensive Some form of sedative is indicated At present we give  $1\frac{1}{2}$  to 3 gr of Pentobarbital Under the existing organization a member of the anesthesia service sees the patient and issues this order and the one for the next morning, which usually calls for Pentobarbital two hours before operation and morphine and scopolamine one hour later, the doses depending on the case Most patients arrive at the operating room drowsy, some are sound asleep, and a few remember nothing until late in the afternoon after the operation

#### ANESTHESIA

With the exception of a few operations under novocain anesthesia, the entire series has been done with nitrous oxide and oxygen In the early years this was reinforced by two preliminary doses of morphine and scopolamine For a short time Avertin was tried as a basal anesthetic, supplemented by nitrous oxide and oxygen Our present routine seems satisfactory, particularly since the adoption of more up-to-date anesthesia machines containing carbon-dioxide filters

In our former operating rooms the use of ethylene and cyclopropane was unsafe because of the danger of explosion Since the opening of our present operating suite in June, 1938, the Trustees have granted us permission to use cyclopropane From experience in other hospitals we believe this to be the most satisfactory agent at present, since with this gas it is possible to use a very high percentage of oxygen and still get good relaxation Intratracheal anesthesia has been used in some of the intrathoracic goiters where there was tracheal deviation or narrowing

During the operation the anesthetist keeps a record of the blood pressure, pulse and respiration

If at any time the condition becomes alarming it is his duty to notify the surgeon The anesthetist has the power of final decision as to whether or not the operation shall be completed in one or two stages

A few patients in our series were fully awake on reaching the operating room despite their premedication, and could not be controlled with nitrous oxide and oxygen We never hesitate to return such patients to the ward and schedule them for another day, with heavier premedication This is a much wiser procedure than operating on a highly excitable patient Poor relaxation increases the technical difficulties, and patients in this excitable state do not do well postoperatively

#### OPERATION

After anesthesia is begun the patient's neck is hyperextended, the skin prepared and the field draped The line of incision is injected with a 1 per cent solution of novocain A collar incision is made 2 or 3 cm above the sternal end of the clavicle, its width varying with the size of the goiter and the length of the neck The skin and platysma muscle are divided, and as one layer the flap is dissected upward to the top of the thyroid cartilage and the lower flap is freed downward All bleeding points are clamped and tied At this stage the edge of the upper flap is grasped with a tenaculum and is held by an assistant

The fascia is next divided vertically from the thyroid cartilage to the suprasternal notch between the edges of the sternothyroid muscles The ribon muscles are freed from the surgical capsule by blunt dissection and retracted laterally In the early years of this series these muscles were cut across, but for some years this has not been done except in special cases where a wider exposure was necessary We believe that division of the muscles predisposes to complications and tends to cause deformity of the neck

Before dislocating the lobe forward and mesially it is important to clamp and tie the middle thyroid veins If this is not done troublesome and uncontrollable bleeding may result The lobe can then be grasped with hooks, rotated, and the areolar tissue and muscle stripped from the posterolateral surface of the gland Downward traction with the index finger inside the capsule and sweeping about the upper pole will usually bring the latter forward into the wound The pole may be ligated at once or double-clamped, leaving a small bit of gland After resection the pole is transfixed by a suture and anchored to the tissues covering the lateral wall of the thyroid cartilage This prevents retraction of the branches of the superior thyroid artery

Next the suspensory ligament is divided, and also the pyramidal lobe, if present. The isthmus is divided and the lobe resected from within outward, making traction outward, with the index finger held behind the lobe to control bleeding. Very little of the trachea should be exposed, and a definite attempt to preserve a strip of the posteromesial surface of the lobe must be made so as to protect the recurrent laryngeal nerves and the inferior group of parathyroids. On the outer surface of the lobe the true capsule may be divided at a slightly higher level. This aids in reconstructing the lobe after resection.

The type of gland and the degree of toxicity determine the amount to be resected. This varies from two thirds to seven eighths of the total. Patients are restored to physiologic function with very little thyroid tissue remaining. Comparatively few become myxedematous, and these are readily controlled by thyroid extract. It seems preferable to risk this possibility rather than a persisting toxicity due to insufficient removal. Our tendency before experience taught otherwise was to do inadequate resections.

At this point in the operation all clamped bleeding points should be tied. More and more we have practiced ligating the inferior thyroid artery on one or both sides, until now it is an almost routine step. This is done close to the carotid artery after division of the deep cervical fascia. In no case have we found any resultant dysfunction. The outer capsule of the resected lobe is then turned toward the median line and the reconstruction of the lobe is completed by continuous or mattress sutures. The opposite lobe is treated similarly. A small rubber drain is inserted to the bed of the wound and the ribbon muscles are closed with interrupted sutures. Formerly ties and sutures were of catgut. For the past year fine silk has been used for ties and slightly heavier silk for sutures. There seems to be definitely less reaction from silk, and there is less postoperative accumulation of serum in the wound.

The neck is then slightly flexed and the skin flap is replaced with Michel clips. It is unnecessary to suture the platysma separately. The use of clips results in excellent scars. We remove half the clips and the drain in twenty-four hours, and the remainder in forty-eight hours. If they remain longer small areas of necrosis develop beneath the points of the clips and the scar is not satisfactory.

In patients with a discrete single adenoma we have been satisfied with enucleating the adenoma or doing partial lobectomy. In toxic adenomas with hyperplasia a subtotal thyroidectomy is in-

dicated. Where adenomas exist it is well to remove all pathologic tissue. This may amount to a subtotal thyroidectomy, but even in non-toxic patients sufficient normal thyroid usually remains to maintain the metabolic level.

#### POSTOPERATIVE CARE

The patient is accompanied to the ward by an intern, who sees that the proper orders are recorded. Good nursing at this stage is invaluable. The fact that the head nurses on the service have acquired considerable experience with thyroid patients has made our problem much simpler.

Since quiet is essential, isolation has been practiced so far as possible. Morphine and other sedatives are not given by the clock, but only as needed to prevent restlessness. Fluids are given by mouth since nausea is not prolonged and a great deal of liquid can be absorbed in spite of nausea and vomiting. Fluids containing Lugol's solution are also given by rectum for twelve hours. Intravenous glucose solution is given in the sicker patients, occasionally with the addition of Lugol's solution. A semi-solid diet is given the day following operation, and increased to full diet by the second or third day.

Most patients are co-operative. This is partly due to the fact that the surgeon has seen the patient before operation, and has advised him in advance what to expect in the way of postoperative discomfort and routine care.

The temperature is normally elevated to about 100°F following operation. Both pulse and temperature tend to reach normal about the third day. As soon as this occurs we allow patients with uncomplicated cases to stay out of bed for short periods, but do not urge them to do so. The average day of discharge is the seventh. Dressings are simple. If serum accumulates in the wound it is released with a fine probe. Healing takes place promptly. After discharge, patients return to the service for dressings and are referred to the Thyroid Clinic for further checkups.

#### ANALYSIS OF RESULTS

The distribution of cases in recognized pathological groups is given in Table 1. Women outnumbered men 6:1. The total number of toxic cases—nodular, diffuse and recurrent—is 374. The number of toxic nodular cases, 78 (22.8 per cent) of 342 primary cases, is considerably higher than that found in other reported series. Also this group usually has a mortality approximately twice that of the diffuse group. We are unable to account for this variation. The classification as nodular is based on pathological reports of adenoma with evidences of hyperplasia. The diffuse cases

also have been classified on the basis of pathological findings

The mortality figures for the period 1925-1937 are reported in Table 2. From 1925 to 1929 the

mortality of toxic cases was 12 per cent, or 6 deaths in 50 cases. Twenty-four of these are classified as bad risks according to the criteria given below. In this period there were 18 two-stage operations and 4 preliminary pole ligations. In all probability these patients, with 4 exceptions, would have two-stage operations today because of the severity of their disease.

Nine of these 50 patients, or 18 per cent, had cardiac manifestations, 3 had evidences of beginning failure before operation, while 4 were

psychotic preoperatively. There were 2 cases of diabetes, one so severe that the patient went into coma twice before operation and showed sugar while getting 90 units of insulin a day. Another patient had severe myasthenia gravis complicating her hyperthyroidism, and died of respiratory failure. One of the patients with cardiac decompensation, fifty-four years of age, suffered in addition from bronchiectasis, and her goiter was substernal. One patient was four months pregnant, with toxic symptoms and severe vomiting which cleared up after thyroidectomy. One patient died on the operating table before the completion of a hemithyroidectomy, a respiratory death which we attribute to the anesthesia. Two of the 3 thyroid storms occurred in 1926. Two other patients in the early group died of cardiac failure. This analy-

sis shows that the mortality in the early period was due largely to the predominance of patients who were poor risks.

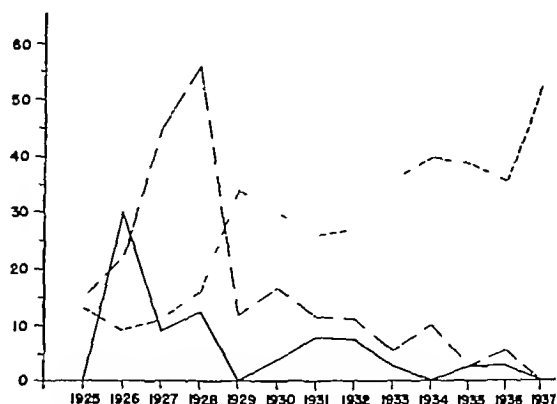

Figure 1 *Analysis of Toxic Thyroid Cases Operated on at the Boston City Hospital 1925-1937*

The dotted line represents the number of cases; the dot and dash line, the percentage of operations performed in stages; the solid line, the mortality rate.

The mortality rates from 1929 to 1937, shown in Table 3, represent a fairer average than do the figures for the entire period. The mortality rate

Non toxic	156	2	1.3
Nodular	143	2	1.4
Diffuse	13	0	—

of 1.7 per cent in 480 cases contrasts favorably with one of 0.6 per cent for my series of 288 private cases in other hospitals. A factor in the low mortality of the latter series was that the patients were entirely under the care of one individual.

#### TOXIC CASES

An analysis of the toxic cases is summarized in Table 4. The poor risks included those with decompensated hearts, those with marked toxicity and poor response to iodine, those with emaciation, and the aged. This group was very rigidly selected, and several cases in which it was felt essential to do two-stage operations rather than risk a fatality are not included. The mortality rate of 23 per cent in this group emphasizes the exclusiveness of the group.

Eighty-five patients (23 per cent) were over forty years of age, a high percentage in a disease that is prone to attack youth and the middle-aged. The

oldest toxic patient was sixty-seven, the youngest twelve

The 11 patients with diabetes did uniformly well, though several were severely toxic. The incidence in our series is approximately three times as high as that reported by other clinics<sup>1 2</sup>. Six of these patients were over forty, and 3 had car-

diac manifestations. One patient with an initial basal metabolism rate of +90 per cent had such severe diabetes that she went into coma on the morning she was to receive a basal metabolism test because of the omission of the morning dose of insulin. Over 700 urinalyses were done while she was in the hospital. Two pole ligations and

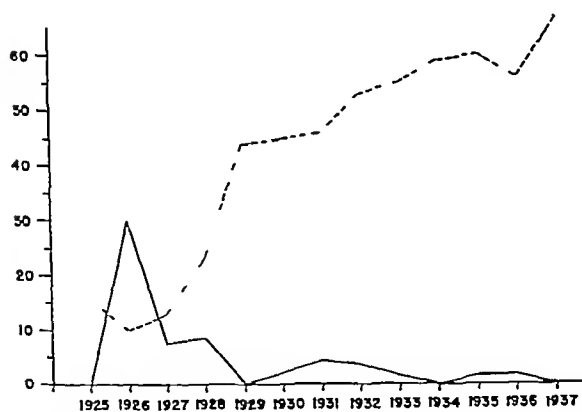

Figure 2. Incidence and Mortality Rates in Toxic and Non-Toxic Thyroid Cases Operated on at the Boston City Hospital 1925-1937

The dotted line represents the number of cases, the solid line the mortality rate

a two-stage thyroidectomy done in 1928 relieved the hyperthyroidism and markedly alleviated the diabetes until 1932, when she was operated on for a recurrence. The basal metabolism rate in 1937 was +7 per cent. Another patient had had three thyroidectomies elsewhere before coming to us with recurrence. Another went into coma a day after operation despite every effort to regulate her diabetes. One patient had a fasting blood sugar of 500 mg per cent on admission.

Most of the 11 psychotic patients were seen in

consultation by the Neurological Service and the diagnosis was confirmed by them. With one exception their psychotic symptoms disappeared within two weeks after operation. The greatest difficulty experienced with these patients was to keep them in the hospital until operation. They all had an untoward fear of operation, and 2 patients who were markedly toxic and psychotic left the hospital against advice without surgery, despite all attempts at dissuasion by the house staff and relatives. It is interesting that 2 patients came to us after temporary commitments in a psychopathic hospital, one six months and the other eight weeks previously, for "extreme nervousness".

Patients with cardiac complications constitute a group in which, as is generally recognized, the risks of surgery are great. Of the 34 patients with cardiac disease 4 died as a direct result of cardiac dysfunction, a mortality of 12 per cent, viewed in another light, 4 of the 12 total deaths, or 33 per cent, were due to cardiac failure.

It is difficult to classify the cases with cardiac complications. There were 6 cases which showed evidence of decompensation preoperatively, of these 3 were fibrillating. Eleven more were fibrillating but showed no other evidence of failure. Three patients were classified as having enlarged hearts and as fibrillating. One case was diagnosed as thyroid heart, 2 as hyperplasia with fibrillation, and 1 each as cardiac hypertrophy, angina pectoris, arteriosclerotic heart disease and aortic regurgitation. Eleven cases were diagnosed clinically as rheumatic heart disease on the basis of enlargement and the presence of aortic and mitral murmurs, this group is interesting from the point of view of diagnosis, and a heated debate ensued over a case in which Dr Ohler and Dr Soma Weiss felt that the aortic and mitral murmurs were not inconsistent with the heart of long-standing hyperthyroidism. Their contention seemed to be borne out by the autopsy findings, inasmuch as the heart valves were filmy and without evidence of pathologic change.

I am convinced that any patient with heart disease and the added burden of hyperthyroidism, even though it is apparently mild, is in urgent need of having the extra burden relieved by surgery. This applies also to adenomas which are clinically non-toxic. I have seen several cases of heart disease in which the removal of non-toxic adenomas resulted in improvement of the cardiac condition. The probable explanation is that any adenoma, however benign pathologically, may undergo mild toxic changes, involute and possibly revert to toxicity. This conforms to our knowl-

edge of the changes in the diffuse toxic type of gland, and it cannot be said that we know that an adenoma is harmless, aside from the possibility of malignant change

The number of patients in the entire series treated by stage operations was 42, or 11.2 per cent. The number so treated dropped off markedly from the period 1925-1929, and in 1937 there were no two-stage operations. This does not mean, however, that we think that such operations can be entirely dispensed with. There is a definite indication for them in poor risks, especially young adults with marked toxicity in whom the likelihood of storm is suggested by a rise in pulse to over 160 during the first part of the operation.

The cases of substernal goiters numbered 32—14 toxic and 18 non-toxic. An interesting feature of these cases was that all but four patients were over forty. There was 1 case of atelectasis and 1 fatal case of pneumonia in the non-toxic group. In practically all these cases the pretracheal muscles on one or both sides were cut to facilitate exposure. It is important as a safeguard against hemorrhage to ligate the blood supply preliminary to delivery of the gland.

An analysis of the 12 deaths in the toxic group shows them to fall largely in the categories of cardiac failure (4 deaths) and storm (3 deaths). One death each resulted from pneumonia, anesthesia, myasthenia gravis, glucose reaction and pulmonary embolism. The 2 deaths in the non-toxic group were the result of pneumonia and cerebral embolism respectively.

Among the toxic cases were several with complicating factors which required discernment in their management. It has been our policy to treat thyrotoxicosis first, in the presence of other surgical diseases. A Negress was admitted to our service with a diagnosis of acute appendicitis. She had marked tenderness and spasm in the right lower quadrant, a temperature of 99°F, a white-cell count of 12,000 and a persistent pulse of 120. Careful history disclosed increasing nervousness. There was mild exophthalmos, tremor, and a diffuse enlargement of the thyroid gland, with bilateral bruit. The basal metabolism rate was +33 per cent. The patient was given iodine and had a remission of toxic symptoms, but the abdominal signs did not abate. Surprisingly enough, the pain ceased within two days after the subtotal removal of a hyperplastic gland. It was our impression that the physical findings had been exaggerated by the increased irritability to stimuli accompanying the hyperthyroidism. Biliary colic with jaundice appeared in a patient with thyrocardiac disease while she was receiving iodine preoperatively. For-

tunately her jaundice and pain subsided and thyroidectomy was performed. She refused to return for abdominal exploration. A patient with typhoid fever had severe coincident toxic goiter, as a result of bilateral pole ligation the temperature dropped, and a case with poor prognosis progressed to early recovery.

I do not share the prevalent belief that the basal metabolic rate is a *sine qua non* in the diagnosis of thyroid dysfunction. More than most laboratory tests, it is subject to wide variation depending on uncontrollable factors. Oftentimes it is markedly lower or higher than the clinical findings indicate. One reading should never be accepted as final, and if repeated readings are at variance with the other data in a given case, too much weight should not be placed on them. One patient in our series had all the symptoms of hyperthyroidism, and a basal metabolic rate repeated several times revealed an average reading of -11 per cent. A hyperplastic gland was removed, after which the patient returned to normal, without any symptoms of myxedema and with a basal metabolic rate of -20 per cent.

#### POSTOPERATIVE COMPLICATIONS

The feature of our series which gives us the greatest satisfaction is the low incidence of postoperative complications (Table 5). Hemorrhage,

Table 5 *Postoperative Complications*

COMPLICATION	NO. OF CASES	PER CENT
Psychosis	4	1.0
Thyroid storm	3	0.8
Wound infection	3	0.8
Pneumonia	3	0.8
Atelectasis	2	0.5
Tetany	2	0.5
Mediastinitis	1	0.2
Cerebral embolus	1	0.2
Pulmonary embolus	1	0.2
Scarlet fever	1	0.2
Urinary retention	1	0.2

as we understand the word, was non-existent. In 2 cases there was a bloody ooze which necessitated changing the dressing three times within the first twenty-four hours after operation, but in neither case was there any reaction in the patient's general condition, nor were any efforts to control the bleeding necessary.

The sole transfusion in the entire series was given to a patient who developed mediastinitis and secondary anemia from prolonged sepsis. This was our only case of mediastinal infection. The patient, a woman of twenty-six, underwent a subtotal thyroidectomy on December 6, 1934. Four days later the temperature rose to 102°F, and later physical examination revealed signs of pneumonia, which were confirmed by x-ray. The patient complained of pain under the sternum, and

the fever continued. Slight widening of the mediastinum was noted in subsequent roentgenograms (Fig 3). The wound meanwhile had healed by first intention. Since the patient's condition was not alarming, it was thought that conservative treatment was indicated. By January 5, 1935, the mediastinal shadow had increased considerably, with deviation of the trachea to the right. The neck had become indurated and the wound was bulging. The wound was opened, with the escape of several ounces of creamy pus which on culture showed hemolytic streptococci. Without any attempt to explore the abscess a drain was placed in its cavity. The temperature promptly subsided, drainage ceased in two weeks, and the pa-

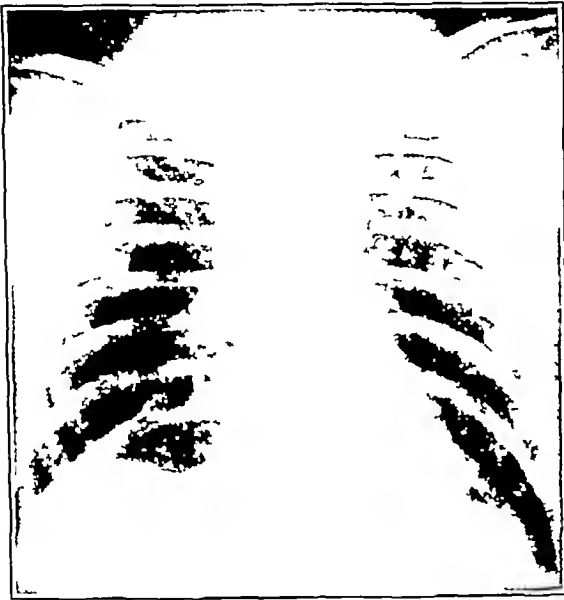

Figure 3

tient was discharged six weeks after her primary operation.

There were only 2 cases of tetany, both were temporary and were relieved by the administration of calcium. Pulmonary complications, including both pneumonia and atelectasis, totaled only a little over 1 per cent. There was 1 case of paralysis of a single vocal cord. In 2 cases the trachea was inadvertently nicked, it was immediately closed with one or two interrupted stitches, including a piece of muscle, and no complications resulted. One of the cases of atelectasis and 1 of those of pneumonia occurred in the non-toxic group, the only other complication in that group was a fatal case of cerebral embolism.

In 17 of the 32 cases of toxic recurrence the primary operation had been performed by us. This is an incidence of recurrence in our series of 4.9 per cent. Although no attempt was made to trace

the whole series of cases we believe that practically all the patients returned to our follow-up clinic and, hence, that this percentage of recurrence is approximately correct.

#### MISCELLANEOUS CASES

Four of the 5 cases of acute thyroiditis, all suppurative and all operated on, occurred subsequent to our report<sup>3</sup> of 10 cases of acute thyroiditis in 1934. A mortality of 50 per cent in these 4 cases, in spite of every effort to save the patients, emphasizes the gravity of the disease. It is interesting to note that 1 of these patients, drained in 1936 with recovery, was operated on at another hospital in 1937 and an intrathoracic malignant tumor of thyroid origin was found. The 5 cases of chronic thyroiditis conformed in general to groups of cases well described in the recent literature. Three were of the Hashimoto type.

The 5 cases of malignancy were undiagnosed before operation, and hence may indicate the percentage that will be encountered in a group of adenomas supposed preoperatively to be benign. They are not an index of the relative incidence of malignancy, since during the period covered by this report there were several cases which were presumptively diagnosed as carcinoma of the thyroid, but which had advanced beyond the reach of surgical therapy.

The single aberrant thyroid was found between the skin and the ribbon muscles, and appeared to be a misplaced lobe, as one lobe was in its normal place and the other was absent.

#### SUMMARY AND CONCLUSION

The development of the management of patients with thyroid disease at the Boston City Hospital is discussed, and a series of 559 cases treated surgically from 1925 to 1937 is analyzed. Interesting aspects, mortality rates and complications are considered.

This series justifies the belief that with adequate organization, plus considerable personal effort, patients with surgical diseases of the thyroid can be satisfactorily cared for in a large municipal hospital.

#### DISCUSSION

DR ISAAC M. WEBBER, Portland, Maine. The financial state of our community in Maine being as restricted as it is, it seems likely that a material number of indigent patients with goiter will be treated in some of our small community hospitals instead of being sent to medical

centers where the last refinement in diagnosis and treatment is available. It becomes the duty of some of us connected with these hospitals to render the best service we can to these unfortunates

On the service at the Maine General Hospital we have endeavored to approximate the good results that have been reported by Dr. Cochrane and others. In a group of 200 consecutive goiter patients surgically treated, 2 succumbed in the hospital. Every patient, regardless of the severity of the thyrotoxicosis or any other complication, was subjected to operation before leaving the hospital.

As to the 2 fatalities, 1 patient had been thyrotoxic for four years, had had two incomplete resections of the thyroid in another hospital, and came to us some three months later in a thyroid storm. After what we believed to be an adequate preparation, she was subjected to operation at which time the greater part of one thyroid remnant was resected with very little difficulty, yet the patient developed a fatal thyroid storm. The second non-survival was an emaciated woman, thyrotoxic for many months, brought to us because of a psychosis, the salient features of which were absolute disorientation and the belief that her food was being poisoned. After an attempt at preparation which was unsatisfactory because of the patient's inability to co-operate, superior pole ligations were performed and later a subtotal lobectomy. The operation resulted in an exacerbation of symptoms which caused death.

As you would surely expect, I think, depleted organic reserve and independent heart disease were the two factors which most frequently caused some of our patients to be placed in the bad risk group. Of 36 patients with varied degrees and types of cardiac damage, 6 had congestive failure at the time they arrived at the hospital, yet all survived thyroidectomy. The major complications relating to surgical technic comprised 3 cases of transient tetany, injury to a single recurrent nerve, and bleeding in 1 case which necessitated reopening of the wound.

In the light of our incomplete knowledge of the etiologic factors in goiter, the impression that I have gained, both from the management of a small group of cases and from the reported experiences of others, is that the present morbidity may be further reduced if some means can be devised whereby patients are brought to proper management and operative treatment before their organic reserve is too badly depleted by long standing thyrotoxicosis.

The management of goiter at the Maine General Hospital in the past seven years has been conducted much as outlined by Dr. Cochrane, therefore his comprehensive analysis of the work done at the Boston City Hospital has been of particular interest to me.

DR. THACHER W. WORTHEN, Hartford, Conn. It is hardly necessary to state that there are certain groups of cases in general surgery for which special assignments produce better than average results. This is particularly true of thyroid surgery and of surgery of the gastrointestinal tract. There are many institutions, however, in which this is a difficult if not impractical arrangement under existing conditions. The problem in such hospitals is that of endeavoring to lift the general average of surgery done for these conditions. Much will depend on the initiative and ability of the operator, but in general hospitals it seems to me that if left to these two factors alone satisfactory progress will not be made.

A third factor can be brought into play which in our experience during the past four years has seemed to produce satisfactory results, that is the annual report to the staff of a detailed analysis of all hospital deaths, grading them with reference to avoidability, to investigation, to preoperative and postoperative care, to operation, to consultations, to records, and so forth. When this is done, the mortality rate in those groups in which it was too high will drop and there will be fewer avoidable deaths. For example, our total hospital mortality rate for thyroidectomy in cases of toxic diffuse thyroid disease was about 3 per cent, individual groups of cases treated by certain surgeons being lower. The group of toxic nodular thyroid disease presented a mortality well under 2 per cent. There was an incidence of malignancy of 1 per cent in our series of 893 cases.

Dr. Cochrane's excellent results are a splendid tribute to his individual effort. It is noteworthy that he has no recorded case of damage to the laryngeal nerve or of hemorrhage.

In spite of the reporting of excellent mortality rates and few complications, there remain the problems of recurrences, of cases that are not benefited in any way by thyroidectomy, and of iodine fixation at high basal rates, which is with us an increasing rather than a diminishing factor.

DR. DAVID W. PARKER, Manchester, N. H. We have had a considerable series of cases for a small hospital, and sometime I hope to report them. The iodine fast cases, referred to by Dr. Worthen, are particularly distressing and hard to prepare for a safe thyroidectomy. I think that we as a group can do something about this. Iodine is too generally used by the family physician when he sees a toxic thyroid. I think that if he could be impressed with the fact that the administration of iodine is absolutely dangerous except as a preoperative measure, we should accomplish a great deal in reducing the number in this bad risk group of iodine fast cases.

ELECTROCARDIOGRAPHIC CHANGES IN VITAMIN B<sub>1</sub> DEFICIENCY\*

CECIL C DUSTIN, M.D.,† HENRY WEYLER, M.D.,‡ AND C PURCELL ROBERTS, M.D.§

PROVIDENCE, RHODE ISLAND

SEVERAL patients recently admitted to the Rhode Island Hospital with clinical evidence of vitamin B<sub>1</sub> deficiency showed abnormal electrocardiograms that might be interpreted as indicative of serious myocardial disease, but under a high-vitamin regime the patients recovered within a few weeks.

Electrocardiographic abnormalities in patients suffering from vitamin B<sub>1</sub> deficiency have been observed and reviewed by various writers. Little emphasis, however, has been placed on the possibility of confusing the electrocardiographic changes found in certain cases of beriberi cardiovascular disease with those found in other myocardial disturbances. Aalsmeer and Wenckebach<sup>1,2</sup> studied the cardiac aspects of beriberi among the inhabitants of Java. Electrocardiograms were normal except for a shortening of the conduction time and tachycardia. The P-R interval was 0.12 second or shorter. It returned to normal during convalescence. There was increased skin resistance, even greater than that found in myxedema, although the deflections were normal or much larger than normal. Keefer,<sup>3</sup> referring to another article published by Aalsmeer and Wenckebach, notes that they also found right ventricular preponderance in some cases. In this country Scott and Herrmann<sup>4</sup> described negative T<sub>1</sub> and T<sub>3</sub>, and said that some patients showed left and others right ventricular preponderance. Moreover, they called attention to the low voltage and to slight aberrations in the ventricular complexes. In 1 of their cases they noted a greatly prolonged R-T interval. Keefer,<sup>3</sup> reporting a series of cases in Peiping, China, stated that there were no characteristic changes in the electrocardiogram, although there was some evidence of myocardial disease. He described low voltage, right and left ventricular preponderance and negative T waves. Weiss and Wilkins<sup>5,6</sup> also found abnormalities of the T waves, low amplitude prolongation of the electrical systole (Q-T) and sinus tachycardia. In addition they noted changes indicative of coronary or myocardial disease, these complexes returned to normal with adequate vitamin B<sub>1</sub> intake. Some of these abnormalities were

found before and some after treatment was begun. As the patients improved following the administration of vitamin B<sub>1</sub> they showed increased utilization of oxygen, slowing of blood flow, diuresis, slowing of the heart rate, increased vital capacity and a decrease in the size of the heart, but the electrocardiographic abnormalities were the last to disappear. Zoll and Weiss<sup>7</sup> were able to reproduce many of the abnormal variations in an experimental study on rats kept on a diet deficient in vitamin B<sub>1</sub>. Moreover, normal electrocardiograms were re-established after a definite vitamin B<sub>1</sub> intake. Feil<sup>8</sup> found similar but more variable changes in a group of patients with pellagra, namely inversion of the T waves in Lead 1 or 2 or both, a Pardee type of S-T with large T waves. Both electrical and mechanical systoles were prolonged. Weiss and Wilkins<sup>6</sup> suggested that these abnormalities were due to deficiency of vitamin B<sub>1</sub> rather than to that of other fractions of the vitamin B group. Their reason was that similar changes were induced in rats with vitamin B<sub>1</sub> deficiency and in patients without pellagra.

We are presenting several cases with histories of unbalanced diets and clinical evidence of vitamin B<sub>1</sub> deficiency. These patients all showed abnormal electrocardiograms. The group comprises 6 male patients ranging in age from thirty-four to fifty. All gave a history of habitual use of alcoholic beverages, usually beer, and concurrently a deficient diet. All entered the hospital because of swelling of the legs and some dyspnea. Two also had swelling of the abdomen. In only 1 case was there a complaint of substernal discomfort, the sensation was of questionable significance and occurred long after the onset of symptoms and electrocardiographic changes. Four patients did not show patellar or Achilles tendon reflexes, and in 1 these reflexes were sluggish. There were sensory abnormalities such as hypesthesia and paresthesia in 2 cases, and a recent history of transient paralysis of the right arm in 1. All but 1 patient received a high-vitamin diet, and all received vitamin B<sub>1</sub> medication. In 2 cases the heart sounds showed notable changes with treatment, in 1 of these a gallop rhythm disappeared soon after entrance. In 3 cases marked reduction in the size of the heart was demonstrated, either by percussion or by x-ray examination, as treatment progressed. In 1 case slight enlargement

‡Resident cardiologist, Rhode Island Hospital.

was shown by x-ray early in treatment but no film establishing the return to normal could be obtained subsequently, and in 1 case the persistent enlargement was thought to be related to hypertensive heart disease. Estimations of total protein of the blood were normal except in 2 cases, in which the percentage was slightly below 50 gm per cent. In only 1 case was there definite anemia, hypochromic in type, and this responded to treatment during the hospital stay. All patients exhibited a weight loss of from 8 to 28 pounds, the average being 18.4 pounds in twelve days, concurrently with reduction of edema. Only 1 patient received digitalis in addition to vitamin therapy.

#### CASE REPORTS

*Case 1* A D, a 39-year-old French Canadian cloth examiner, entered the hospital November 26, 1937, because of swelling about the ankles and enlargement of the abdomen. For 6 months he had been drinking some whiskey and twenty to thirty glasses of beer a day. He had been eating only two meals a day and taking very little fruit or green vegetables. He had suffered no sub-sternal distress. There was no orthopnea, but for a short time he had noticed dyspnea on exertion.

On admission the temperature was 99°F, the pulse 100 and the blood pressure normal. The apex impulse of the heart was palpable in the fifth left intercostal space 10 cm from the midsternal line. The sounds were of good quality. There were no murmurs. The peripheral arteries were not thickened. There was shifting dullness in the flanks of the abdomen, and a slightly tender liver edge could be felt 2 fingerbreadths below the costal margin. There was slight pitting edema around the ankles. Patellar and Achilles tendon reflexes were absent.

The patient was placed on a high-vitamin and high protein diet, and starting on the 2nd day was given by mouth and intravenously about 9 mg of vitamin B<sub>1</sub> daily\*. An x-ray on the 7th day showed a slight increase in the size of the heart shadow, with evidence of chronic passive congestion in both lung roots. There was no free fluid in the pleural cavities. By the 12th day edema was practically absent and the patient was out of bed. The weight changed from 188 pounds on the 2nd day to 180 pounds on the 13th.

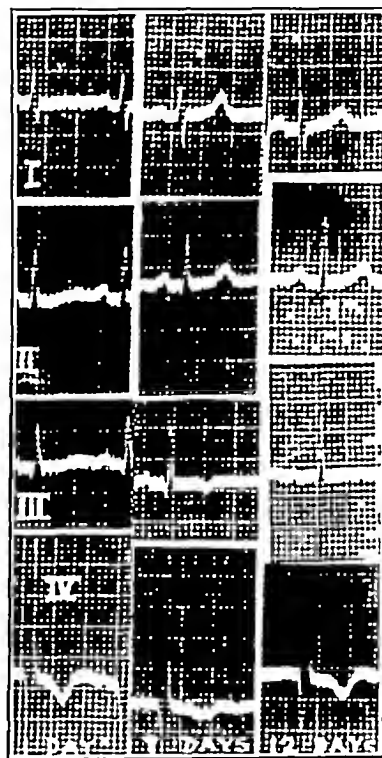

This patient presented electrocardiographic changes (Fig 1) that are of interest, on admission the record showed flattening of the T waves, a low voltage and a rapid rate. These alterations became much less marked within a very few days. He was not clinically very sick, although the first record might give that impression.

The urine was free of albumin. Glucose tolerance tests were normal. The galactose tolerance test 4 days after admission showed no excretion (normal excretion is from 0 to 3 gm). The hippuric acid excretion test, done 1 day after admission, was 22 per cent of normal, 11 days later, during diuresis, it was 80 per cent, and 2 days later it was 58 per cent. Thus although the galactose tolerance test was normal the hippuric acid test showed some evidence of decreased liver function. The fact that the liver function test improved following diuresis seems to indicate that the decreased liver function was due to cardiac decompensation and passive congestion. The fact that

the blood cholesterol was not low—it was 276 on admission and 184, 13 days later—corroborates this interpretation. Phenolsulfonephthalein excretion showed a total of 65 per cent. There was no anemia and the blood smear was normal. Blood chemical determinations were within normal limits. An icteric index was normal.

The patient was discharged from the hospital on the 18th day.

*Case 2* J K, a 36-year-old, unemployed Irishman, entered the hospital on August 9, 1937, complaining of swelling of the legs and cough for the last 2 weeks. For the last 10 years he had drunk large amounts of alcohol, and for the last 2 years had been eating poorly, taking

Bazett's K = 0.420

0.390

0.400

Figure 1 Case 1

Note later increase in height of T waves (precordial leads by old method)

almost no meat. There had been frequent episodes of delirium tremens. For the last few months he had become progressively weaker, and dyspneic on the slightest exertion. He could not lie flat without discomfort. He had at no time suffered pain in the chest and had not noticed palpitation. Only once previously had he noticed swelling of the legs. This subsided after bed rest.

On entry the patient was obviously dyspneic. A few rales were heard at the base of the right lung. The blood pressure was 128/80. By percussion the left cardiac border was measured 8 cm from the midsternal line, just within the midclavicular line. The apex impulse was felt in the fifth interspace. The cardiac rate was 110, the action regular and the sounds of good quality. The liver was not felt. The hands, thighs and lower legs showed pitting edema. No reflexes could be elicited in the legs.

\*Betalin S (Lilly) synthetic vitamin B<sub>1</sub> was used in all cases

After the 1st day the patient began to receive a well rounded diet and about 10 mg of added vitamin B<sub>1</sub>. By the 3rd day the edema of the legs had disappeared, although on the 5th day a little sacral edema was still present. By the 8th day the patient was allowed to be out of bed. At the end of 2 weeks there was no clinical evidence of myocardial disease and the patient complained of no pain whatsoever. The blood pressure on the 14th day was 132/98. The weight dropped from 123 pounds on the 2nd day to 110 pounds at the end of 2 weeks.

Tests for syphilis were negative. The urine showed an occasional trace of albumin. Morphological and chemical blood studies showed nothing abnormal except a slightly lowered blood protein on admission. This became normal by the 10th day.

The patient was discharged on the 21st day.

**Case 3** J. V. G., a 34-year-old Irish bartender, entered the hospital on October 14, 1937, complaining of shortness of breath and swelling of the abdomen and ankles.

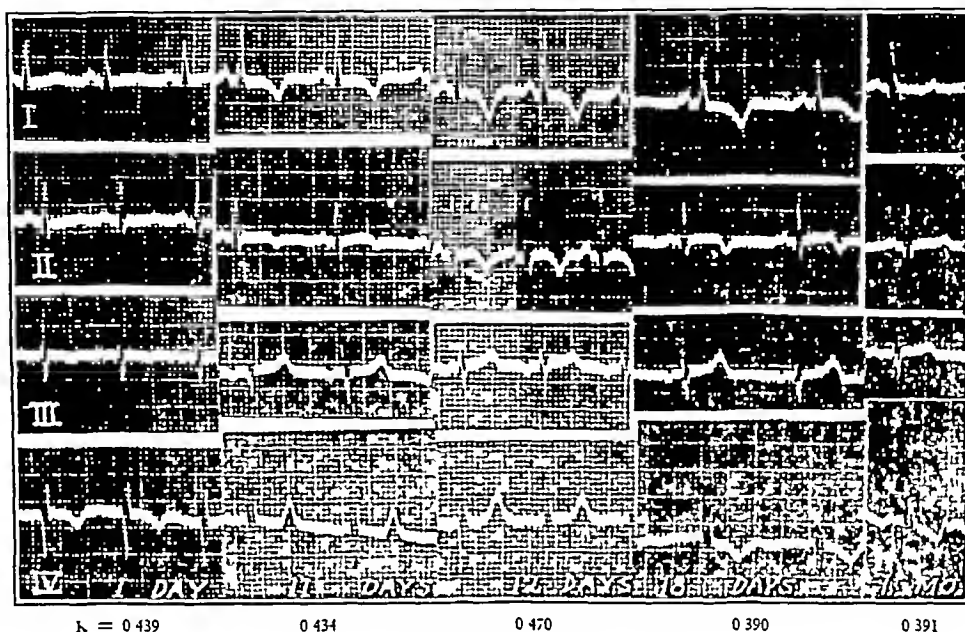

Figure 2 Case 2

*Note return of T waves to normal after marked inversion Q<sub>4</sub> wave persistently present (precordial leads by old method)*

The first electrocardiogram (Fig 2) was not normal for a young male adult. The rate was rapid and the ventricular complexes showed absent or flattened T waves. In 10 days, coincident with definite clinical improvement, the electrocardiogram had changed to such an extent that it could well be mistaken for that of an anterior coronary occlusion. The abnormality increased somewhat and then showed a slight trend toward a more normal condition. On the patient's discharge, when he was clinically well, the electrocardiogram was decidedly abnormal, even in the chest lead, which generally in this series of cases showed little disturbance. A record made 7 months later was similar to the first in this study.

An x-ray film on admission showed slight diffuse enlargement of the heart shadow with congestion about the lung roots. No fluid was found in the costophrenic angles. A week later a film showed the same increase in the heart size, but an improvement in the pulmonary congestion. Orthofluoroscopy on the 12th and 21st days confirmed the persistent slight enlargement of the heart suggested by x-rays, the cardiothoracic ratio being 12.8 to 23.3 cm and 12.5 to 24 cm respectively. The heart was globular in shape, and there was moderate dynamic dilatation of the proximal portion of the aorta. On a return visit 7 months later, orthodiagraphy showed the same measurements.

Laboratory findings showed that the serological reac-

tion of 3 weeks duration. For the last 15 years the patient had frequently taken as much as a quart of liquor a day. Three years previously he had had some swelling of the ankles. For the last 3 years he had been a bartender and had been taking his meals irregularly. One month before entry he had begun to notice shortness of breath on climbing stairs, and shortly after this, swelling about the ankles and enlargement of the abdomen.

On examination the blood pressure was 130/90. By percussion the heart was apparently of normal size. No murmurs were made out. The second pulmonic sound was equal in intensity to the second aortic sound. In the abdomen there appeared to be fluid in the flanks, and the liver reached below the costal margin, as was judged by percussion. There was pitting edema of both legs. The patellar reflexes were absent. There were no sensory disturbances.

At entrance the patient was given a high-carbohydrate and low-fat diet, with added vitamin B<sub>1</sub>. On the 4th day the diet was altered to contain more protein. The patient received no diuretic. The course was afebrile. The blood pressure remained low—120/80 on the 12th day and 90/60 on the 18th. By the 6th day the edema had begun to clear and by the 11th day it was gone. The patient was up and about the ward by the 21st day.

An x-ray of the chest on the 4th day showed a transverse enlargement of the heart shadow, and evidence of

marked congestion in the lung fields (Fig 3 C-1) On the 11th day re-examination of the chest showed clearing of the lung fields, and the heart appeared smaller

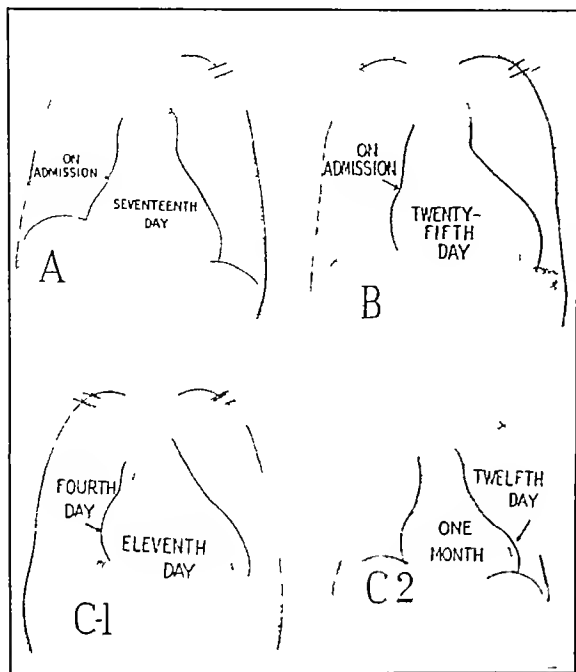

Figure 3 Diagrams to Indicate Shrinkage in Size of the Heart with Therapy

A represents Case 4 B, Case 5, and C-1 and C-2 Case 3

On the 12th day fluoroscopy showed that the diaphragm moved normally The heart was very slightly enlarged to the left (Fig 3 C 2), and the aorta not widened The

Electrocardiograms showed that during treatment the heart rate became slower but the abnormal ventricular complexes were intensified, finally the record became confined within normal limits (Fig 4) There were no clinical findings to account for the unusual changes in the electrocardiograms

Laboratory findings included a negative Wassermann test, evidence of a slight hypochromic anemia, and normal protein, urea, glucose and cholesterol determinations Galactose tolerance and hippuric-acid tests were normal The urine was normal except for an occasional trace of albumin

The patient was discharged on the 23rd day

**Case 4** J L, a 45-year-old Italian laborer, entered the hospital December 22, 1937, complaining of swelling of the legs and ankles and shortness of breath for the last 3 weeks He had given up work as a laborer He had been drinking beer, at times in excess, and his dietary habits had been poor The temperature on admission was 98.6°F, the pulse 80, the respirations 20 and the blood pressure 120/80

The apex impulse of the heart was palpated in the fifth left intercostal space 8 cm from the midsternal line, and by percussion there seemed to be enlargement. The sounds were faint and muffled. The lungs were clear The liver could not be felt below the costal margin. There was slight pitting edema from the ankles to the knees The patellar and Achilles tendon reflexes were sluggish, while others were hyperactive.

In the hospital the patient received a high vitamin diet, with about 10 mg of vitamin B<sub>1</sub> added daily By the 9th day he was up and about without recurrence of edema On entrance an x ray film showed an elevated right diaphragm and a heart shadow moderately enlarged in its transverse diameter, and apparently displaced to the right (Fig 3 A) No free fluid was demonstrable. Four days later the heart shadow appeared to be of the same size, but subsequent x rays showed a marked diminution in

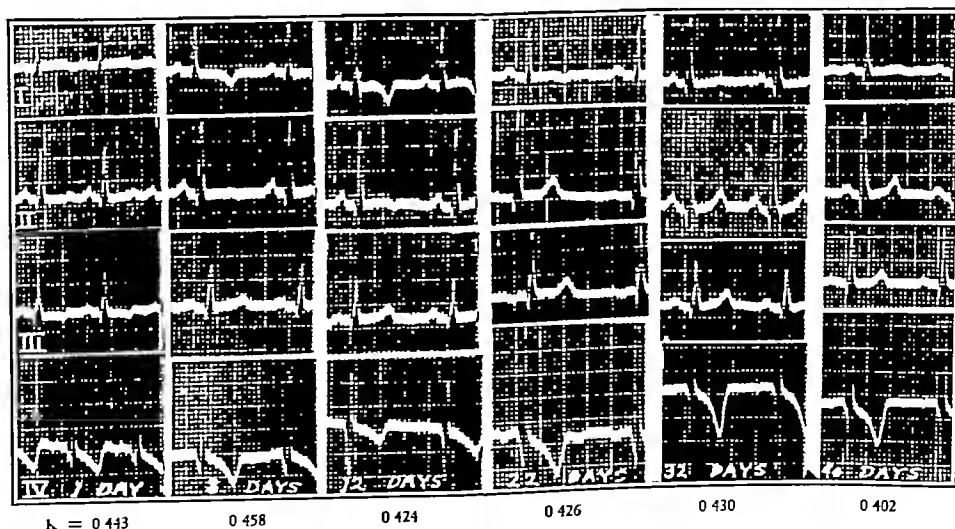

Figure 4 Case 3

Note T<sub>1</sub> and T<sub>2</sub> inversion at eight and twelve days with return to normal later (pre-cordial leads by old method)

cardiac pulsations were feeble. Orthofluoroscopy this same day showed a cardiothoracic ratio of 14.4 to 26.2 cm, and 1 month after entry the heart was further reduced so that the ratio was practically normal, 13.1 to 25.9 cm.

the size of the heart and a clearing of the lungs Orthodiagrams made on the 19th day, 1 day before discharge, showed a cardiothoracic ratio of 11.5 to 25.3 cm, contractions of good quality and slight dynamic dilatation of

the proximal aorta. The course was afebrile. On the 2nd day the patient weighed 145 pounds, but by the 6th day only 118 pounds. The latter weight remained constant during the remainder of his hospital stay.

A series of electrocardiograms showed that the low voltage, rapid rate and flattening of the T waves in the first tracing all changed rapidly toward normal (Fig 5).

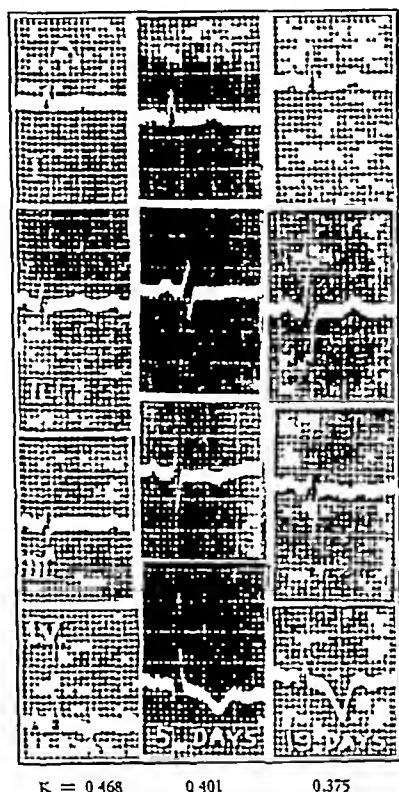

Figure 5 Case 4

*Note increase in voltage and in height of T waves after treatment (precordial leads by old method)*

The second and third tracings showed changes in the ventricular complexes in Leads 2 and 3 that were difficult to explain, particularly as the man was not in any way incapacitated physically, and had no symptoms suggestive of sudden myocardial changes.

Laboratory tests showed only an occasional trace of albumin in the urine and no abnormal blood findings.

The patient was discharged on the 20th day.

**Case 5** E. B., a 41-year-old Irish American truck-driver, entered the hospital July 14, 1937, because of swelling of the legs and ankles for 2 months. There had been three previous hospital admissions. In 1932 there was paralysis of the right arm after a drinking bout, and a lump which lasted until discharge 7 days later. The patellar and Achilles tendon reflexes were hyperactive. In December, 1932, he was readmitted because of painful joints, but had no fever. No abnormal findings were noted in the heart. Malnutrition was present. In July, 1936, he re-entered the hospital because of ankle edema and dyspnea. The blood pressure was 150/80. The heart was slightly enlarged to the left. There was a systolic murmur over the left side of the heart, and the

x-ray silhouette suggested mitral stenosis. The liver was felt 3 fingerbreadths below the ribs.

On July 14, 1937, the patient again complained of shortness of breath on exertion, and swelling of the legs. He had noticed palpitation. He gave a history of excessive beer-drinking, but asserted that he had been eating three meals a day in restaurants. He admitted no ataxia or paresthesia. The blood pressure was 120/80. There was a tremor of the tongue. Only occasional rales were noted at the lung bases. The heart seemed to be much enlarged to the left, and a definite gallop rhythm was heard. There were no definite murmurs. The rate was 120 and the action regular. The sounds were only of fair quality, and at one examination there appeared to be both systolic and diastolic apical murmurs. The liver was not felt. There was edema of the abdominal wall to the costal margins, and also of the back, legs and scrotum. No patellar or Achilles tendon reflexes were obtained, and there was impaired sensitivity to pain in the lower legs.

The patient was given digitalis for 9 days and ammonium chloride three times a day for 6 weeks. Besides a high-vitamin diet, he received 10 mg. or more of vitamin B<sub>1</sub>. On the 3rd day he received 1 cc. of Salyrgan. By the 4th day, the lungs were clear and the edema was nearly gone, some remaining in the genitals. One week after admission the heart sounds were noted to be much stronger, with only a very soft apical systolic murmur remaining. The second pulmonic sound was louder than the second aortic sound, and accentuated. The blood pressure was 160/110. Furthermore, the heart seemed definitely decreased in size by percussion. The former gallop rhythm had disappeared. At the end of 2 weeks there was no pulmonary or peripheral edema. The heart was slow and regular, and the sounds were of good quality. The left border of the heart was 11 cm. from the mid-sternal line. The patellar tendon reflexes were still absent, although there was less numbness in the legs. On the 17th day an x-ray showed definite decrease in the size of the heart. Toward the end of the 4th week the patient complained of palpitation. After 1 month in the hospital he mentioned a feeling of constriction in the left chest, and seemed unduly excited by the interest shown in his condition. After 6 weeks he was allowed to be up and about the ward, at which time a marked weight loss was evident. There had been a loss from 165 pounds on the 6th day to 137 pounds at the end of 1 month. The latter weight remained constant until discharge, after nearly 2 months in the hospital.

On entrance, an x-ray film showed a large left ventricle and an increased supracardiac shadow (Fig 3 B). There was passive congestion of the lower two thirds of the lung. Five days later there were practically the same findings. Fourteen days later there was clearing of the hilar shadows but still a slight diffuse enlargement of the heart. Twenty-three days later there was a definite decrease in the size of the heart, with clearing of the lungs and no remaining supracardiac widening. Orthofluoroscopy on two occasions after this time indicated that subsequently the heart remained constant in size and was well within normal limits, the cardiothoracic ratio being 12.5 to 27.5 cm.

A series of electrocardiograms covering a period of 6 weeks showed changes that might be mistaken for those due to coronary occlusion (Fig 6). On the previous admission a year earlier the record showed a rapid rate, low voltage and increased electrical systole. These conditions improved during treatment. On this admission, after 1 week of treatment, although the patient was clinically well the tracing was quite abnormal. During the re-

mainder of the study the electrocardiograms returned to normal. The patient showed little clinical evidence of serious heart disease, such as might have been expected from the electrocardiographic changes.

Laboratory studies showed nothing abnormal except an occasional trace of albumin in the urine and a moderate secondary anemia, which disappeared before discharge.

**Case 6** H A G, a 50 year-old German boxing instructor, entered the hospital September 4, 1937, complaining of swelling of the legs and eyelids for 10 days. The patient gave a history of drinking ten to twenty glasses of beer daily for the past 6 months and neglecting his meals. He had recently noticed shortness of breath on exertion.

to be enlarged to the left. Orthofluoroscopy on three occasions showed no significant change in the cardiovascular shadow over a period of more than 2 months. Elevation of the right diaphragm continued to be present, as well as dynamic dilatation of the proximal aorta. The cardiothoracic ratio averaged 136 to 265 cm.

The first electrocardiogram tracing, although quite unusual, should probably be considered within normal limits (Fig 7). In 5 days the previously high T waves had flattened to the lower limits of normal. In succeeding records the ventricular complexes showed a trend toward the form seen in the first record.

Other laboratory findings were negative.

The patient was discharged on the 16th day.

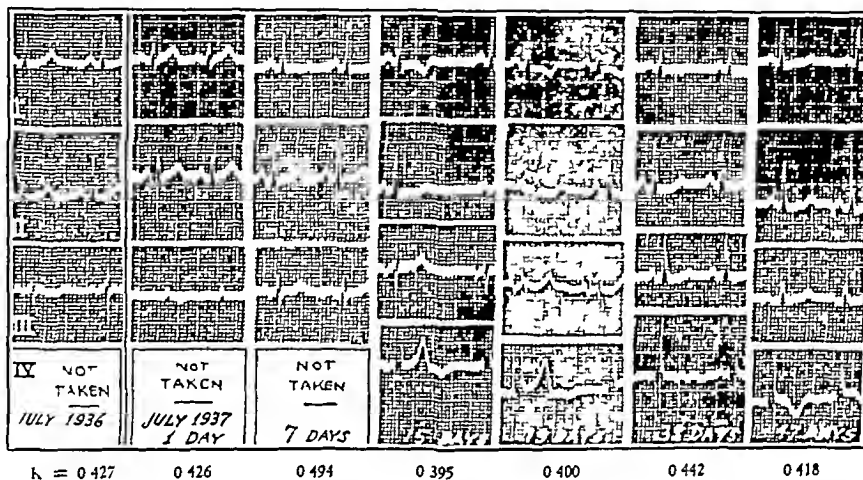

Figure 6 Case 5

Note return of inverted T waves to normal changes in  $T_4$ , but constant presence of  $Q_4$  (precordial leads by old method)

There was trembling of the hands. For several days the right hand and foot had been numb, without noticeable ataxia. There was no pain in the chest.

The blood pressure was 170/90. At both lung bases moist rales were present. The apex impulse was found in the fifth left intercostal space 11.5 cm from the mid sternal line. The action was regular, with a rate of 84 and an occasional extrasystole. The second aortic sound was louder than the second pulmonic sound and there was a soft systolic murmur at the apex. The first heart sound was somewhat booming. The liver edge was not palpable and there was no ascites. The legs showed no motor or sensory disturbance, but there was moderate pretibial edema, with none in the feet or over the sacrum.

The patient was given a diet high in protein and vitamins, with about 10 mg of vitamin  $B_1$  added. Forty-eight hours after admission the edema was entirely gone and the lungs were clear. By the 4th day the patient developed delirium tremens and was sent to the disturbed ward. He had then a rectal temperature of  $104^\circ\text{F}$ . On the 5th day the venous pressure was 39 mm of water and the circulation time by the ether method was 9, 9 and 75 seconds respectively. The blood pressure remained elevated, being 150/100 at discharge. The patient lost 15 pounds in 11 days, weighing on the 4th day 158 pounds and on the 15th day 143 pounds. Except for the episodic fever of  $104^\circ\text{F}$  the course was afebrile.

X-ray films of the chest on entrance showed the left lung more radiant than the right and the right diaphragm elevated as if due to an enlarged liver. The heart seemed

#### COMMENT

Each case in this series was followed by repeated electrocardiograms at rather close intervals while under treatment. In the chest leads the old method was used. The common features seen on admission were increase in the electrical systole, according to Bazett's formula, a rapid rate and a tendency to low voltage, and in most cases a flattening of the T wave in Leads 1, 2 and 3. The chest leads showed the least tendency to become abnormal. In subsequent records, during treatment, all cases showed a slowing of the rate, an increase in the voltage and varying changes in the ventricular complexes. The changes in the ventricular complexes during treatment occurred quite rapidly, usually within a few days, curiously, as treatment progressed, during the first week or two the electrocardiograms became more abnormal and then tended to return toward normal (Figs 2, 4 and 6). The abnormal ventricular complexes changed more rapidly than would be expected in coronary disease.

We have observed similar rapid changes in several conditions, such as acute nephritis, acute

pericarditis and diabetic acidosis. Similar observations in acute nephritis have been made by Master, Jaffe and Dack.<sup>10</sup> Recently we have seen

interpretation of the electrocardiograms in some cases might easily be entirely incorrect. In a few cases coronary occlusion, except for the chest lead, would undoubtedly have been suspected. In 1 case two electrocardiograms had been made a year previously. Re-examination of these records showed an increase in the electrical systole, although at that time the clinical diagnosis of vitamin deficiency was not made, apparently because it was not considered in the differential diagnosis. Increased electrical systole is common to all these cases. Barker, Johnston and Wilson<sup>11</sup> have reported a series of cases showing increased electrical systole which they attribute to hypocalcemia. We have observed a case of acute nephritis, without vitamin deficiency, in which the electrical systole was increased but the blood calcium was normal.

T-wave changes, as described, may be caused by several conditions, and it is necessary, in interpreting electrocardiograms, to know the clinical findings.

Heart Station, Rhode Island Hospital, Providence.

## A JACKET FOR THE TREATMENT OF SCOLIOSIS\*

HAROLD G LEE, M.D †

BOSTON

AN appliance designed by the writer for the treatment of scoliosis, after having been in use for nine years, has proved to be efficient both as a corrective and as a supportive measure (Fig 1)

This brace, while embodying the same principle of overcorrection as does the Abbott jacket, has certain advantages that make it a more acceptable

ent, the existing curve can be lessened, if not actually corrected (Figs 2 and 3) An improvement in balance can also be established by the development of secondary curves, the brace meantime preventing the sagging or increase of the primary curve that results in a loss of height (Figs 4 and 6) The possibility of correcting, or at least of preventing, the increase of early scoliotic curves

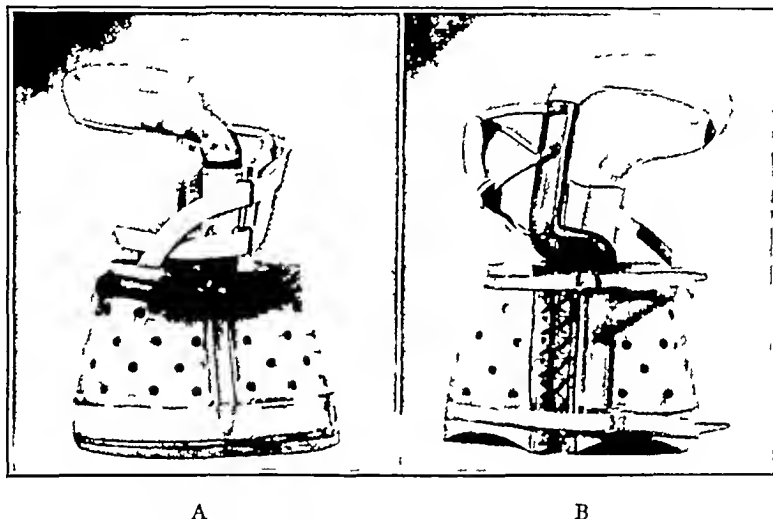

Figure 1 *Brace for the Treatment of Scoliosis*

form of treatment In the first place, the brace is applied with the spine extended, rather than in the flexed position necessitated by the Abbott technic Secondly, pressure is exerted by means of a flexible elastic strap rather than by plaster of Paris As the result of these modifications, discomfort from the position, as well as an unsightly appearance, is avoided, furthermore, there is no compression of the chest, distortion of the abdominal organs or interference with the circulation The brace can be worn under the regular clothing and be kept on at night On the other hand, it is easily removed to permit bathing and exercise Because of the light construction of the appliance, patients do not complain of its being uncomfortable during warm weather

Treatment by means of this jacket is most efficacious in the years of active growth, that is, between the ages of ten and fourteen In the early stage of scoliosis, when the spine is still flexible and only slight accommodative changes are pres-

ent, the existing curve can be lessened, if not actually corrected (Figs 2 and 3)

and of establishing better balance is a plea for the early recognition of these cases

In the later stages, when the curve is fixed and cannot be corrected, further strain and slumping can be prevented by the use of the brace In these cases, care must be taken that the patient wears the brace for a sufficiently long period The brace has been used successfully in controlling the development of curvature in cases of infantile paralysis, but, again, the corrective efforts must be long continued The jacket works well in cases of scoliosis that eventually come to operative fusion Before fixation, the curve is corrected and the balance improved as much as possible by the use of the brace, and following operation, the brace is used to secure the maximum correction while fusion is taking place (Fig 5)

A plaster-of-Paris cast is used as a model for the construction of the jacket This cast is taken with the patient standing, while a head piece exerts slight traction The arm on the low side of the body is raised straight in the air, taking

Figure 4 X Ray Photograph of Case L G

This shows the end result of holding a dorsal curve by the brace during the actively growing years while a secondary curve developed Note that both curves are about equal in size

Figure 5 X Ray Photograph of Case N F

The spine is being held in the corrected position while fusion takes place

a part of the body weight, and the other is held at an angle of 45 degrees to the body

The brace is so constructed that absolute rigidity—a most important factor of an appliance of this kind—is obtained. A pelvic girdle of leather that is bound top and bottom with steel

when it is pulled into place, exerts constant pressure over the point of greatest convexity of the curve. Both the lateral and rotary curves are influenced by this pressure.

Treatment by means of this brace must be carefully supervised. It must be worn until the patient

Figure 6 X-Ray Photographs of Case F M

*A was taken before the brace was applied to hold the dorsal spine while a secondary curve developed, note that the ribs are practically impinging. B shows the corrective effect of the brace note the separation of the ribs*

bands ensures fixation of the pelvis. Two steel uprights extend from this girdle, one from the back and one from the front. A heavy steel crutch that is 5 cm in width and reinforced with leather connects these uprights. The front upright has a goose-neck curve to allow the pelvic girdle to be laced in front. It is also equipped with an outrigger that is carried well forward of the chest to allow for expansion. To this outrigger and to the back upright is attached an elastic strap that is about 10 cm in width.

When the jacket is applied, the low shoulder is forced upward by the crutch. The elastic strap,

is beyond the flexible deforming age, and in some cases, two or three years may be necessary. While the brace is being worn, the customary therapeutic measures, such as exercise, are carried out.

During the past nine years, 76 patients have been treated by the application of this brace. Twenty-nine of these patients had flexible curves that were correctible. Forty-one had severe structural curves, and in these cases the brace was used to prevent further strain and sagging. In the treatment of a group of 6 cases of spinal fusion, the brace proved to be of decided advantage.

412 Beacon Street.

## REPORT ON MEDICAL PROGRESS

### HODGKIN'S DISEASE AND ALLIED DISORDERS\*

HENRY JACKSON, Jr †

BOSTON

THE title of this review is intended to include Hodgkin's disease, lymphosarcoma, reticulum-cell sarcoma and the so-called giant-follicle lymphoma. The word "allied" should not imply that the various pathologic conditions are necessarily related in their etiology or, for that matter, in their pathogenesis. They are allied, if you will, merely because they are diseases primary in the lymphoid tissues of the body, because their etiology is as yet unknown and because they present similar clinical pictures and have a similar course. For many purposes, these conditions may be grouped under one general heading, that of malignant lymphoma. Where a finer distinction between the subtypes is of genuine value to the practitioner, mention of that fact will be made.

#### HISTOLOGY

Space does not permit a searching analysis of the histopathological characteristics of each type of malignant lymphoma. Each may, however, be briefly defined.

In lymphosarcoma, the lymph nodes or other organs are diffusely invaded by lymphocytes, mature or, more rarely, immature. There is often notable involvement of the capsule and extensive invasion of adjacent organs. The condition may exist in conjunction with lymphatic leukemia. Indeed, the interrelation between lymphosarcoma and lymphatic leukemia is so intricate and so unpredictable that the two diseases may well be regarded, for practical purposes, as one and the same.

In reticulum-cell sarcoma, the diseased organs and nodes are invaded and destroyed by large, pale cells with vesicular nuclei and scattered chromatin. These cells, distinctly larger than even immature lymphocytes, are actively ameboid and irregular in shape. The cytoplasm is faintly acidophilic and considerable in amount. Eosinophils are not found. Fibrosis is rare. Invasiveness is common and often extreme.

Hodgkin's disease may be profitably subdivided into three types: lymphoma, granuloma and sarcoma.

In Hodgkin's lymphoma, the architecture of the involved lymph nodes is diffusely replaced by

mature lymphocytes, among which are scattered a few, or more rarely many, typical Reed-Sternberg cells. There is neither eosinophilia, fibrosis nor necrosis. Careful study may be necessary to distinguish this form of Hodgkin's disease from lymphosarcoma. The differentiation is, however, of much practical importance.

The pleomorphic histological picture of Hodgkin's granuloma is familiar to all. There is fibrosis, often extreme, eosinophilia, necrosis with polymorphonuclear leukocytic infiltration, and, of course, typical Reed-Sternberg cells, without which the diagnosis cannot be properly made.

In Hodgkin's sarcoma, the involved tissues are invaded by large cells of uniform size and with considerable basophilic cytoplasm. The nuclei are round, and present characteristically a prominent nucleolus. There is neither fibrosis nor true necrosis, though dead cells may appear here and there. Eosinophils are not found. Some cells are multinucleated and there are scattered typical Reed-Sternberg cells, a *sine qua non* for the diagnosis, as in the case of Hodgkin's granuloma and lymphoma.

Hodgkin's lymphoma may with the passage of time take on the full histological characteristics of Hodgkin's granuloma. Furthermore, the latter may, more rarely, become malignant, excised tissue then showing areas indistinguishable from Hodgkin's sarcoma. We have fibroid phthisis, classic tuberculosis with cavity formation and miliary tuberculosis, so we have Hodgkin's lymphoma, Hodgkin's granuloma and Hodgkin's sarcoma. The prognostic implications of these finer subdivisions of Hodgkin's disease will be discussed subsequently.

In giant-follicle lymphoma,<sup>1</sup> the lymph nodes are studded in both cortex and medulla with large germinal centers composed of uniform, rapidly multiplying cells of uncertain origin. The absence of necrosis, polymorphonuclear neutrophils and phagocytosis serves to distinguish this condition from simple inflammation. This type of malignant lymphoma frequently progresses into one of the other varieties, whether it be Hodgkin's disease, reticulum-cell sarcoma or lymphosarcoma.

#### ETIOLOGY

The etiology of these diseases is unknown. There is still, indeed, much dispute as to whether

\*From the Thorndike Memorial Laboratory, Second and Fourth (Harvard) Medical Services, Boston City Hospital, the Department of Medicine and the Collis P. Huntington Memorial Hospital, Harvard University.  
†Assistant professor of medicine, Harvard Medical School.

they should be regarded as neoplastic or infectious<sup>2</sup> It is probable that lymphosarcoma and reticulum-cell sarcoma are true neoplasms and owe their origin to the obscure causes of such conditions The frequent presence of inflammatory processes close to the site of these tumors has led some investigators to believe that chronic infection may play a role in their origin On the other hand, it is thought by many that Hodgkin's disease is a true infectious granuloma Certainly, as Ewing has said, "Tuberculosis follows Hodgkin's like a shadow" It has never been established, however, that the tubercle bacillus is of etiologic importance For the present, the cause of malignant lymphoma in all its varied forms remains obscure

#### AGE INCIDENCE

Malignant lymphoma spares no age<sup>3</sup> There are certain important differences, however, in the age distribution of the various types Hodgkin's disease—whether Hodgkin's lymphoma or Hodgkin's granuloma—is very evenly distributed through the first six or seven decades It is virtually as common in the fifties as it is in the teens This fact is often overlooked

The age distribution of reticulum-cell sarcoma is quite different Very low in the first and second decades, the incidence rises rapidly and steadily to a peak in the sixth, only to fall as rapidly again A similar age distribution is found in the Hodgkin's sarcoma group—the incidence, in short, of malignant disease in general The lymphosarcomas show a high peak in the second decade (22 per cent of all cases) and a second peak in the late fifties and sixties (52 per cent of all cases) The disease is rare in the first and third decades Giant-follicle lymphoma may occur at any age

All forms of malignant lymphoma are commoner in men than in women

#### GROSS PATHOLOGY

The most important thing to remember in regard to the pathology of these diseases is that virtually any organ may be involved, either grossly or microscopically This simple fact explains the extraordinary protean character of the symptomatology of the malignant lymphomas In general it may be said that, with certain important exceptions, the lymph nodes are almost invariably enlarged, either in the cervical, axillary, mediastinal, abdominal or inguinal regions The spleen and liver are very commonly involved, and in decreasing order of frequency the pancreas, gastrointestinal tract, bones, skin, lung, heart, nasopharynx, breast, ovary and testicles Involvement of the central nervous system is not rare

Particular reference should be made to three

systems other than the lymphatic Secondary deposits in bone occur in some 25 per cent of all cases of Hodgkin's disease<sup>4</sup> Similar involvement is uncommon in reticulum-cell sarcoma, and rare in lymphosarcoma In Hodgkin's disease, the initial symptom may be due to destruction of bone,—even in the absence of obvious lymph-node involvement,—and the unwary physician may attribute the attendant pain to some hypothetical orthopedic condition and so fail to recognize the fundamental disease More commonly metastatic bone lesions occur late in the disease Although they are usually painful, extensive destruction may occur without pain and be discovered only by routine x-ray examination

Malignant lymphoma of one form or another involves the gastrointestinal tract in approximately 25 per cent of all cases<sup>5</sup> Such lesions are oftenest found in the stomach, duodenum or small intestine, less frequently in the large intestine or rectum Unfortunately they are frequently multiple, and only rarely does one encounter isolated lesions that are susceptible of surgical removal

Mediastinal involvement is frequent and well recognized It is not so commonly appreciated that there may be diffuse parenchymatous infiltration of the lung, which may simulate a chronic non-suppurative pulmonary lesion<sup>6</sup>

#### CLINICAL PICTURE

It is highly important to recognize that the clinical symptomatology of this group of diseases is a most varied one Almost any sign or symptom may appear By far the commonest initial symptom is a painless lump, most often in the neck, much less commonly in the axilla and rather rarely in the inguinal region There follows, in order of frequency, pain (commonest in the abdomen, back or legs), fatigue (unaccompanied by other symptoms), persistent sore throat, dyspnea, cough, fever, loss of weight, generalized itching and amenorrhea Rarer initial symptoms are hoarseness, pain in the chest, diarrhea, paraplegia, hemoptysis, hematemesis, nasal obstruction, tinnitus, edema of the legs, anorexia, vomiting, deafness and melena

The first symptoms vary in their relative frequency from group to group of the subdivisions Eighty-five per cent of patients with Hodgkin's lymphoma complain initially solely of a painless lump This symptom is present at onset in about three quarters of all patients with Hodgkin's granuloma, but in only one third of those with Hodgkin's sarcoma or reticulum-cell sarcoma Pain is never present at the onset of Hodgkin's lymphoma but is found early in some 10 per cent of Hodgkin's granulomas, 25 per cent of lymphosarcomas and Hodgkin's sarcomas and nearly 40 per cent of

reticulum-cell sarcomas These figures merely reflect the relative invasiveness of the individual types of lesions

The fact that the enlarged lymph nodes are so often painless, together with the fact that not infrequently they appear following an acute upper respiratory infection and not rarely decrease or even disappear temporarily with subsidence of the infection, often lulls both the patient and the physician into a false sense of security It must be remembered that in adults persistent enlargement of lymph nodes in absence of obvious cause is very rarely due to chronic inflammation alone

As has been intimated above, the symptomatology is extremely varied, and once the disease has set in almost any symptom or sign may arise Yet long periods of quiescence may follow appropriate radiation therapy, and this fact should not be construed as indicating actual freedom from disease

Certain special features of the clinical picture should be referred to Generalized itching without obvious cause may for some time be the only symptom of Hodgkin's granuloma It is occasionally accompanied by a gradually increasing generalized bronzing of the skin, most marked in the axillary and gluteal regions<sup>8</sup>

Skin lesions of the most diverse sorts may appear early or late in the course of any of the malignant lymphomas<sup>8</sup> The association of bizarre skin lesions with lymphadenopathy should always arouse suspicion that one may be dealing with some form of malignant lymphoma

Fever is common in Hodgkin's granuloma Indeed it is rare to have a case of this disease run its course without an increased temperature at one time or another Most frequently the fever is irregular, rising at night to 100 or 103°F and falling to normal in the morning Occasionally one encounters the so-called Pel-Epstein type of fever, in which the temperature rises daily over a period of a week or more, eventually reaching 103 to 105°F, and subsides as steadily and evenly to normal, only to rise again after a period of one or two months Gradually the episodes of fever become longer and the intervals of freedom shorter Once the temperature remains continually elevated, death is not far off Such fever may be for months the only sign of the disease<sup>9</sup>

The bone lesions so frequently appearing in malignant lymphoma have already been referred to Their x-ray appearance is not diagnostic Any bone lesion occurring in the course of generalized malignant lymphoma may properly be regarded as due to that disease Their advent in Hodgkin's disease is usually heralded by pain in the involved bone or referred to the nearest joint Occasionally

when the vertebrae are destroyed, paraplegia and cord-bladder result Bone lesions are of very serious prognostic importance, for death usually ensues about one year after their demonstration by x-ray except in cases in which the sternum is involved The latter may do very well indeed

Particular reference should be made to primary reticulum-cell sarcoma of bone<sup>10</sup> This condition, which has only recently been recognized as a clinical entity, may occur at any age Most frequently the long bones are involved, especially the femur, tibia and humerus The clavicle is also a not infrequent site. The disease has in the past been mistaken for osteogenic sarcoma, Ewing's tumor, osteomyelitis and syphilis The dangers of such erroneous diagnoses are obvious Pain is the commonest symptom The tumor grows quite slowly, and may reach massive size without seriously affecting the general health of the patient In no other bone sarcoma is the contrast between the well-being of the patient and the size of the lesion so marked The x-ray picture is not distinctive Early there is mottled rarefaction of the bone. Later there is massive destruction, often with pathologic fracture Although the tumor is radio-sensitive, it would appear that the most effective treatment is amputation followed by prophylactic radiation In 11 of 16 cases subjected to amputation the patients were alive and well from six months to fourteen years after onset Seven were alive and apparently free from disease ten years after onset<sup>10</sup>

#### LABORATORY EXAMINATION

Neither reticulum-cell sarcoma nor giant-follicle lymphoma gives any distinctive blood picture, although a moderate degree of normocytic anemia may be seen in the former

The relation of lymphosarcoma to lymphatic leukemia has already been alluded to Occasionally a case may start as a pure lymphosarcoma and, with the passage of time, develop the classic blood picture of lymphatic leukemia Much more rarely the reverse is true In the latter cases, usually as a result of intercurrent infection, the white-cell count falls to normal and the differential becomes normal In many cases of lymphosarcoma the percentage of lymphocytes in the peripheral blood is increased

In Hodgkin's disease—of whatever type—sooner or later there are almost always changes in the peripheral blood picture The white count is often moderately elevated (15,000 to 25,000) or more rarely depressed (500 to 3000) In either case the polymorphonuclear neutrophils are likely to be elevated They may be markedly so (85 to 96 per cent) In rare cases the monocytes are increased

to a high degree (15 to 50 per cent) Eosinophilia exists rarely. A definitely abnormal white-cell picture in Hodgkin's disease usually indicates that the condition is widespread. A normocytic normochromic anemia almost always develops as the disease advances. The red-cell count may fall as low as 500,000. Not infrequently levels of 1,000,000 to 2,000,000 are reached. In absence of acute blood loss, anemia of this degree is extremely rare in any other type of lymphoma.

In all types of malignant lymphoma, the basal metabolic rate is elevated if the disease be sufficiently widespread. Levels of +20 to +50 per cent are not unusual, and even +110 per cent has been recorded. Determination of the metabolic rate is therefore of some diagnostic value.

A biopsy of one of the lymph nodes should be done whenever feasible. Without such a diagnostic procedure no accurate diagnosis can be made, and an accurate diagnosis is always of practical value to both the patient and the physician. It is important, however, to observe certain rules. An entire node should be removed. Cutting into a lymphomatous mass or removing part of a node may spread the disease. It is important to remove a node of sufficient size to assure an adequate histological picture. Small satellite nodes frequently show only chronic inflammation. Most important of all is the question of tissue fixation. A poorly fixed and stained section is worse than useless. It is remarkable how difficult it may be to make even a tentative diagnosis from poorly fixed tissue, and how easy it may be to make a specific and definite diagnosis when the same tissue is adequately prepared. If possible the tissue, in thin slices, should be immediately fixed in Zenker's fluid, run through paraffin and stained with eosin and methylene blue. If the patient is to be sent to one of the larger medical centers for treatment, it is as well to defer biopsy until it can be done in the hospital to which he is referred.

#### TREATMENT

It is a moot point whether surgery should ever be attempted in the group of malignant lymphomas, except for primary reticulum-cell sarcoma of bone, already referred to. In this disease it would appear to be unquestionably indicated. Many authorities believe that malignant lymphoma is always a generalized disease and that surgical intervention with a view to cure is therefore contraindicated. If, however, a case of Hodgkin's disease, particularly of the lymphoma type, be sharply limited to one area in the neck, if the patient's general condition be good and if the peripheral blood picture, sedimentation rate and basal metab-

olism be normal, it would seem proper to attempt the complete removal of the involved tissue. Such a procedure has been known to have resulted in "cures" of fifteen to twenty years' duration, but these cases are few and even after this lapse of time one cannot be entirely sure that the patient is free from disease. Still, radical surgery is worth attempting in carefully selected cases. In expert hands there can be but little danger. If the disease be truly limited and accessible, cure is possible.

X-ray therapy remains the standard method of treatment. The details of dosage should be left to the radiologist. There is some difference of opinion as to whether only obviously involved areas should be treated or whether all lymph-node-bearing regions should be subjected to radiation even though they do not appear to harbor any pathologic lesion. Jacob, Peirce and Hildreth<sup>11</sup> and Desjardins<sup>12</sup> advocate the latter or generalized form of therapy. The majority of workers believe that radiation should be applied to diseased areas only. The usual custom is to give from 200 to 800 r at 250 kilovolts in divided doses to the involved regions, repeating this dosage only when and if further indications arise, either by symptoms or by signs. In treating very large lymphomatous masses, especially those in the neck, mediastinum or abdomen, considerable caution must be exercised, for the first reaction of the diseased tissue is to swell, and thus strangulation may occur, furthermore, the rapid destruction of a large mass may flood the system with catabolic products capable of producing profound deleterious effects.

If there be marked anemia, blood transfusions must be resorted to before x-ray therapy is undertaken. The existence or development of leukopenia calls for extreme caution in radiotherapy.

Many authorities have held that x-ray therapy does not prolong life. This may be true if one considers only the average of a large series of treated and untreated cases, but there can be no doubt whatever that in individual cases life is materially prolonged,—this is particularly true of mediastinal involvement,—and Peirce, Jacob and Hildreth<sup>11</sup> appear to have shown conclusively that the life of even the average patient is materially longer after appropriate treatment. It may therefore be said that radiation is of very real and practical value, but that the details of such therapy should be left to a competent and experienced radiologist.

One must not lose sight of the fact that general medical care is of distinct value. Adequate food and plenty of fresh air and rest undoubtedly help. Iron in the form of ferrous sulfate is indicated in

the presence of anemia, although one should not anticipate any startling benefit unless there is an accompanying iron deficiency due to inadequate diet, bleeding or poor absorption. All obvious foci of infection should be removed and the greatest care taken to avoid any upper-respiratory infection. There is some evidence that vitamin D in large doses may be beneficial.

#### PROGNOSIS

In the average case of malignant lymphoma the patient lives two and a half years from the onset of symptoms. But no individual patient is the average, and, as has been indicated above, the various types of lymphoma carry with them quite different prognoses.

The average duration in the case of lymphosarcoma is slightly over two years, 80 per cent of the patients are dead within three years, very few survive more than ten years, although approximately 20 per cent live from three to ten years after onset.

Similarly, the average life of patients with reticulum-cell sarcoma is somewhat less than two years, and 17 per cent live from three to ten years, yet 2 per cent are alive and apparently free from disease from ten to twenty years from onset. Into the latter group fall patients with primary reticulum-cell sarcoma of bone appropriately treated.

In Hodgkin's disease, we find the most interesting data as to prognosis. The average duration of life from the first symptom in Hodgkin's lymphoma is two and a half years, yet nearly 30 per cent survive five years or longer, and nearly 20 per cent ten years or longer. In contrast, the average case of Hodgkin's granuloma lasts but a scant two and a half years and very few patients survive for over ten years, nearly three quarters are dead within three years. No individual with

Hodgkin's sarcoma has in our experience survived a three-year period, the majority are dead within a year. This fact is entirely in accord with the neoplastic and invasive character of the condition.

It is difficult to give with any degree of accuracy the duration of the disease embraced under the term giant-follicle lymphoma, since this type so often progresses into one of the others, at which time it of course takes on the prognostic implications of that type. In general, however, it may be said that cases of giant-follicle lymphoma have a better prognosis than the other types, save only Hodgkin's lymphoma. The average duration is four years, many patients live from six to twelve years.

\* \* \*

Malignant lymphoma is a protean disease whose signs and symptoms are legion. The intermittently progressive course may be prolonged and the symptoms alleviated by appropriate treatment. True cures, if they occur, are rare, yet this fact should not prevent our using to the fullest extent all those measures now at our disposal for combating this dread condition.

### CASE 25011

#### PRESENTATION OF CASE

A fifty-two-year-old, white, married bus driver was admitted complaining of epigastric pain.

Four and a half months before admission he experienced the gradual onset of a sensation of pressure under his xiphoid and fullness after meals. Increasing constipation began at the same time. He gradually stopped heavy foods and overeating and drank more and more milk. Activity made him feel quite well, whereas resting gave an increased sense of pressure in the epigastrium. Four weeks preceding entry pain was first noted in the form of steady, severe epigastric pain about two hours after meals, when he believed he could not take food. Hot water bottles gave him the most relief. During this time his stools were yellow, never bloody or tarry. Two weeks before admission he noted increased gaseous distention and at 2 a.m. was awakened by pain which was not relieved until the hot water bottle had been applied for a half hour. This pain recurred from time to time. It did not radiate, did not extend to the back or shoulders and was not cramping in nature. The patient worked during the last week and on the fourth day developed an upper respiratory infection. Three days before entry he saw a child killed, this completely unnerved him. He had not vomited and had not had jaundice or abnormal stools. He had had no urinary symptoms.

For the past six months he had been relatively deaf in the right ear but had had no symptoms of otitis. Two years before he had had a transurethral prostatectomy, and eight years before that a tonsillectomy. At the age of seventeen years he had had typhoid fever.

Physical examination showed a thin, chronically ill man with evidence of weight loss. A hard 2 cm nodule was palpated in the region of the left anterior cervical lymph nodes. Both the infraclavicular and supraclavicular fossas were depressed. Examination of the chest was negative. The blood pressure was 100 systolic, 65 diastolic. There was moderate tenderness over the midepigastrium, but no palpable masses or organs. Rectal

examination was negative. The extremities were negative.

The temperature was 100.6°F, the pulse 110, and the respirations 20.

The urine examination was negative. The blood showed a red-cell count of 5,000,000 with 90 per cent hemoglobin, and a white-cell count of 17,000 with 80 per cent polymorphonuclears, 18 per cent lymphocytes and 2 per cent mononuclears. The serum nonprotein nitrogen was 19 mg per cent, the protein 5.8 gm, and the chlorides were equivalent to 98 cc of N/10 sodium chloride. A blood Hinton test was negative. Gastric analysis on two occasions showed no free acid, even after histamine. Four stool examinations were guaiac positive.

X-ray films of the gastrointestinal tract showed an irregular swelling involving the prepyloric region of the stomach, as well as the first and second portions of the duodenum. The third portion showed some swelling in its proximal portion. Questionable ulceration was present in the second portion. There apparently was ulceration in some of the involved areas, particularly in the lower part of the second portion of the duodenum where there was an irregular cavity, filling only at times. The third portion was at times narrowed and when filled showed an apparent pressure defect on the outside. The adjacent loop of jejunum showed localized swelling. This lay several loops distal to the ligament of Treitz but in close proximity to the third portion of the duodenum. The involved area was sharply defined and was approximately 7 cm in length. This part of the jejunum was rigid and its mucosal pattern destroyed, apparently due to ulceration. Its position was fixed. There was probably an extraluminal soft-tissue mass pressing on the duodenum. Transport through the small intestine was delayed. The ileocecal valve was not reached at the end of five hours.

On the fifth hospital day the patient vomited some greenish coagulated milk. On the tenth day a walnut-sized node was palpated in the right lateral chest wall. He vomited again on the tenth night. The stools were guaiac positive. He was having no pain. On the thirteenth day he had a chill and epigastric pain, and felt weak and feverish. The pain did not radiate to the shoulders. The temperature was 102°F. The abdomen was tense. He vomited, but the vomitus did not contain blood. The following day he vomited 200 cc. of greenish liquid. During the next two weeks his temperature varied between 98.6 and 102°F daily. His condition remained essentially unchanged.

On the thirty-third hospital day an operation was performed

### DIFFERENTIAL DIAGNOSIS

DR WALTER BAUER From the history alone one can say that we are dealing with a man of fifty-two years of age who had symptoms referable to the upper gastrointestinal tract. There were no symptoms of obstruction. However, it should be pointed out that this man finally placed himself on a diet of soft-solid food and liquids. I gathered that milk had constituted the greatest portion of his dietary. This may be one reason for there having been no symptoms suggesting obstruction. The location of the pain and its character are of no help in deciding in favor of one lesion of the upper abdomen as compared with another. It evidently was a constant pain. My impression is that the pain was more like that encountered in cases of infiltrating lesions of the wall of the stomach or intestine. From the history alone I should have considered cancer of the stomach, ulcer, gastritis and perhaps pancreatitis or cancer of the pancreas as diagnostic possibilities.

From the physical examination we learn that he had lost weight, that a nodule was felt at the lower end of the chain of anterior cervical lymph nodes and that the stools were guaiac positive. With this information one might reasonably conclude that he was dealing with an ulcerating lesion of the gastrointestinal tract. The presence of the nodule plus the weight loss favors the presence of cancer of the upper gastrointestinal tract rather than that of a gastritis or a gastric or duodenal ulcer. The nodule felt in the neck was evidently an enlarged, firm lymph node but not the typical sentinel gland of cancer of the thoracic or abdominal cavity. This finding does not help us appreciably because the patient was of the age group where it is commonly encountered. It may be used, however, as evidence in favor of cancer. I cannot see much reason to suspect that the symptoms in this individual were being caused by any type of infection, such as tuberculosis or regional ileitis. Syphilis might be suspected but it would be difficult to prove that we were dealing with a syphilitic lesion. The question to be answered is, What type of lesion did the roentgenologist observe in this man? From here on I think the differential diagnosis could probably be carried on much better by the roentgenologist than by myself. We must decide whether we are dealing with a malignant lesion of the upper gastrointestinal tract. If so, is it intrinsic or does it represent invasion from a neighboring organ?

I wonder if Dr. Schatzki would show us the

x-rays. I should like to know, first, whether the stomach emptied normally.

DR RICHARD SCHATZKI I do not remember whether it emptied normally. Certainly there was no obstruction at the pylorus. The peculiar thing was that this patient did not have a real pylorus. In other words there was no clear-cut narrowing between the stomach and the first portion of the duodenum, such as usually indicates the position of the pylorus.

DR BAUER Would you say there was involvement of the pylorus?

DR SCHATZKI There is a lesion involving the prepyloric region, and the greater portion of the duodenum, in fact all of it that one can see, that is, the first and second portions and the beginning of the third portion. Needless to say, this is a very unusual appearance. The second portion is perhaps slightly less involved than the first.

DR BAUER Can you point out the ulcer in the second portion of the duodenum?

DR SCHATZKI This area here is ulcerated. There is no mucosal pattern.

DR BAUER That is not duodenum, is it?

DR SCHATZKI It is the junction of the second and third portions of the duodenum. The peculiar thing about the first portion as well as the stomach and immediate prepyloric region is that there are what appear to be folds, but the folds are much thicker than they usually are in this area. They are also much more irregular, and the surface appears to be destroyed.

DR BAUER In other words you would say there is ulceration of a large portion of the mucosa of the duodenum.

DR SCHATZKI Yes, with marked swelling.

DR BAUER With involvement of the jejunum as well?

DR SCHATZKI The jejunum is involved here. The distal part of the third portion of duodenum is not involved and the upper region of the upper loop of the jejunum is not involved, but there is one loop which is in close proximity to the duodenum and shows involvement over an area of 7 cm., with definite destruction of the mucosa.

DR BAUER With an area in between that you think was normal, or was there contiguous involvement?

DR SCHATZKI No, not contiguous so far as the course of the intestine is concerned, though the involved loop was in close proximity to the diseased duodenum.

DR BAUER The disease involved the prepyloric region, the first and second portions of the duodenum and about 7 cm of the jejunum. Is that correct?

DR SCHATZKI Yes

DR AUGUSTUS S ROSE Was a barium enema done?

DR SCHATZKI Not to my knowledge

DR BAUER It would be a help to know whether a pressure defect did or did not exist

DR RICHARD H SWEET There was a definite pressure defect. The other films looked as though the duodenum were pushed aside

DR SCHATZKI You can see the defect around the involved loop, where it was pressed on by the soft-tissue mass. I think I ought to make that clear. This loop has a definite intrinsic lesion in addition to the definite mass that is around it

DR BAUER If I were to be absolutely honest I should be forced to say I cannot make a definite diagnosis. However, I shall proceed as though I could

It is obvious that we must try to decide whether we are dealing with an intrinsic lesion or an extrinsic one that has invaded the previously mentioned portions of the gastrointestinal tract. I do not believe that we have to consider the possibility of a prepyloric carcinoma very seriously, because extensive involvement of the duodenum and ileum does not occur in such cases. If we were to think in terms of cancer outside the gastrointestinal tract which has invaded the upper portion of the tract we should have to consider carcinoma of the gall bladder, pancreas or duodenum. If this patient had involvement of the duodenum secondary to carcinoma of the gall bladder or pancreas he probably would have been jaundiced. In addition we might expect to feel a mass. Primary carcinoma of the duodenum is a very rare disease. If it involves the second portion of the duodenum, it usually arises in the ampulla of Vater. If this patient had this type of lesion we should again have expected to have observed jaundice. The biggest argument in favor of either of these diagnoses is the fact that Dr Schatzki feels quite certain that he was able to demonstrate a pressure defect

I am inclined to stick to the possibility that we are dealing with an intrinsic lesion of the gastrointestinal tract and not an extrinsic one. The one diagnosis that best explains everything in this case is malignant lymphoma of the lymphosarcoma type, even though there is very little on physical examination to substantiate such a diagnosis. He did have one enlarged anterior cervical node and during his stay in the hospital developed a walnut-sized node on the chest wall. The

patient had a fever which is consistent with this diagnosis. He had a leukocytosis, and there were 80 per cent polymorphonuclear leukocytes. This diagnosis better explains the findings in this case than any other that I can think of. I shall say that this patient probably had a malignant lymphoma of the lymphosarcoma type involving the duodenum and a portion of the jejunum

I should like to hear further suggestions or comments

DR TRACY B MALLORY Would anyone care to suggest an alternative diagnosis?

DR BAUER A luetic lesion might be suspected. I can go no further

DR WYMAN RICHARDSON You can have intrinsic malignant tumors of a sarcomatous type other than lymphoma

DR BAUER Yes. I thought of the possibility of leiomyosarcoma because one does encounter cases with several such lesions in the gastrointestinal tract. I did not appreciate, however, that the lesions were quite as extensive as they apparently were in this instance

DR JAMES H MEANS I shall make a statement and must beg of you to believe that I am truthful. As Dr Bauer read this case I did not recognize it as one that I had recently seen. I did not become conscious of that until Dr Mallory handed me the clinical record just now. It seems to bear out what is apparently true, that it is sometimes easier to make a diagnosis from an abstracted record than from seeing the patient. I had no difficulty in making the diagnosis of lymphoma just now, but in looking over the complete clinical record it appears that when the patient went to operation after being under my care, I had not the faintest idea what the diagnosis was. So it would seem that the patient was actually more puzzling than the paper case that has been summarized for this meeting

DR SWEET I should like to elaborate on what Dr Means has said. One clinical aspect which is barely mentioned in the case history and on which our whole attention was focused for the subsequent two weeks was whether he had a penetrating ulcer. On one occasion the surgical resident was summoned to consider whether the patient had to be operated on immediately because he was so tender and had so much spasm in the right upper quadrant

DR BAUER Was this before or after this x-ray evidence?

DR SWEET I do not know. I think I was the first surgeon to see him, and at the time he had spasm and tenderness and all the clinical aspects of a penetrating duodenal ulcer. On going over the history and learning about the absent acidity

and other aspects of the case I considered a penetrating carcinoma, but we finally agreed that he must have a penetrating ulcer. I was ill for a period after that, and Dr Churchill saw him. He made a diagnosis of penetrating ulcer and decided that surgery was indicated after the lesion had quieted down.

The lesion did quiet down, and after a considerable period we operated and found what we thought from gross inspection was an ulcer of the first portion of the duodenum which had penetrated, almost perforated and had been walled off by the adjacent tissues. The liver and adjacent portions of the omentum were adherent and rather edematous, and inflammatory in nature. I thought the course of wisdom was not to disturb this. The astonishing thing was that in the retroperitoneal tissues and in the mesentery he had an immense amount of thickening and a great mass in the base of the mesentery, which was nodular. There were several isolated nodules which looked like enlarged lymph nodes. This mass extended from just above the promontory of the sacrum up along the aorta to the region of the duodenal loop and distorted the second and third portions of duodenum. I took out two lymph nodes, one of which was the size of a small walnut and appeared to be lymphomatous. I then did a gastroenterostomy because of what looked to me like potential, if not actual, obstruction at the pyloric region. I made diagnoses of retroperitoneal lymphomatous tumor and probable duodenal ulcer, which had penetrated. I could not be sure that the mass which I saw and felt in the duodenum was lymphoma.

DR BENJAMIN CASTLEMAN I think it is only fair to the X-ray Department to say that before the operation they made a diagnosis of lymphoma.

DR MALLORY It seems to me the most helpful point in the clinical findings was the total absence of acid in the gastric contents. I think that duodenal ulcer under those circumstances is impossible.

#### CLINICAL DIAGNOSES

Lymphoma of small intestine  
Duodenal ulcer with perforation and abscess?

#### DR BAUER'S DIAGNOSIS

Malignant lymphoma of the lymphosarcoma type, involving the pylorus, duodenum and jejunum

#### ANATOMICAL DIAGNOSES

"Hodgkin's sarcoma" of stomach, duodenum and jejunum

Operative wound anterior gastroenterostomy,  
enteroenterostomy  
Abscess of lung, right lower lobe

#### PATHOLOGICAL DISCUSSION

DR MALLORY We found multiple areas of lymphomatous involvement in the duodenum and jejunum. Two separate areas of jejunum were affected, and there was a considerable degree of erosion in both places at the time he died. However, the mass of retroperitoneal nodes that Dr Sweet noted and biopsied showed no evidence of tumor, and that is a point I think worth emphasizing. I believe that in every case of lymphoma of the gastrointestinal tract which we have seen the regional nodes have been very large but have never shown anything but inflammatory hyperplasia. You cannot biopsy a mesenteric lymph node from a case of lymphoma of the gastrointestinal tract and count on getting histological verification of the diagnosis. Such nodes always show simple inflammatory hyperplasia. That was the case here. The one other finding was a small abscess in his lung, which seemed to be of considerable duration, I think it very likely antedated the exploratory operation.

DR SWEET This man made a quite uneventful recovery so far as the operation was concerned. He was almost ready to go home when he had a massive hemorrhage which was the cause of his death. This to my mind tends to confirm the diagnosis because, in my experience, so many cases of lymphoma of the gastrointestinal tract have had massive bleeding.

DR GRANTLEY W TAYLOR Did the supraclavicular lymph node show evidence of metastasis at autopsy?

DR MALLORY We unfortunately did not examine it.

DR MEANS I think that it ought to be pointed out that the cervical lymph nodes should have been biopsied. That was the glaring error in this case.

DR MALLORY They would probably have been negative. In these cases where lymphoma is sharply localized to the gastrointestinal tract one usually does not find tumor elsewhere.

DR GEORGE A MARKS Is it possible to say that the tumor was primary in the duodenum, or was it all in the mesentery?

DR MALLORY It was in the wall of the bowel in all three areas, with some infiltration of the mesentery as well. We had an argument in the laboratory as to the histological classification of the tumor because it was rather undifferentiated. We thought it was probably so-called "Hodgkin's sarcoma."

## CASE 25012

## PRESENTATION OF CASE

A fifty-five-year-old, white, married Belgian bartender was admitted complaining of chronic, recurrent symptoms of peptic ulcer.

He was perfectly well until twenty to twenty-five years before entry when he developed mid-epigastric pain which occasionally extended through to the back, occurring after meals and regularly relieved by food or alkalis. He had periods of remission and relapse, the latter occurring usually in the early spring and late fall. X-ray films were taken from time to time, the first about twenty years before admission, the last a year before admission. Each time an ulcer was demonstrated. The last films demonstrated a "new" ulcer. During the summer before admission he had his usual remission and was well until six weeks before entry when his autumnal exacerbation began. A Sippy regime gave little relief. The pain was severe, especially at night, so that he could not sleep for more than two hours at a time. He had tarry stools on only one occasion, and this was attributed to medication. There had been no pain in the region of the shoulders or lower abdomen. He had had no nausea or vomiting, and his appetite had been good. He had lost no weight, his best weight being that on admission—170 pounds. Although he was a bartender he stated that he very seldom took a drink. He smoked a moderate number of cigarettes. His work had always been light. His family history was noncontributory.

Physical examination showed a moderately obese male in no distress. Examination of the head, chest, abdomen and extremities was negative. The blood pressure was 160 systolic, 100 diastolic.

The urine examination was negative. The blood showed a red-cell count of 4,880,000 with 90 per cent hemoglobin, and a white-cell count of 11,100 with 67 per cent polymorphonuclears. The non-protein nitrogen of the serum was 22 mg per cent, the protein 6.2 gm and the chlorides were equivalent to 100 cc. N/10 sodium chloride. A blood Hinton test was negative. A gastric analysis showed 55 units of free hydrochloric acid, and the contents were guaiac negative. A stool examination was guaiac negative.

A gastrointestinal x-ray series showed marked constriction of the lesser curvature of the stomach and a deep ulcer crater in the middle third of the lesser curvature, measuring 1.6 cm in depth and 1.7 cm in width. There was moderate surrounding induration, but the mucosa appeared normal except for convergence to the crater. There

was considerable spasm of the antrum and first portion of the duodenum, which showed a slight deformity without evidence of a crater.

During the first six days in the hospital the patient had pain only once or twice daily, which was much less severe than previously, his symptoms being well controlled by a bland diet.

On the eighth hospital day an operation was performed.

## DIFFERENTIAL DIAGNOSIS

DR MARSHALL K. BARTLETT I wonder if Dr Schatzki will show the films?

DR RICHARD SCHATZKI These pictures show exactly what the report describes—a large crater approximately 5 cm away from the pylorus. There is some induration around the crater such as you see in any large ulcer, as well as shortening of the lesser curvature, which is a sign of chronicity. There is also marked convergence of the rugae. In other words the gross picture is that of peptic ulcer.

DR BARTLETT Dr Schatzki has outlined the problem quite clearly. We have an ulcer on the lesser curvature, and we must decide whether it is benign or malignant. One of the interesting points in that regard would be to know whether this recurrent ulcer which this man had had for twenty years had always been in the same location or whether he had formerly had a duodenal ulcer and at entry had a gastric ulcer. I do not see that there is anything in the history that could lead us to assume he had two separate lesions. The only suggestive point is the statement in the history that the x-rays which were repeated periodically before admission showed a "new" ulcer shortly before entry.

What have we in favor of the lesion's being cancerous? We have the facts that he may have had an ulcer in this region for a long time, twenty years, and that he had a relatively large ulcer in the portion of the stomach where we know malignant disease is apt to occur. In favor of its being a benign lesion we have the facts that he was in good general health, had lost no weight, had no anemia and had free hydrochloric acid in normal amounts. The gastric contents were negative to the guaiac test, as was the stool. Of course both were single examinations and are not conclusive, but perhaps they are slightly helpful. In addition to that we have the x-ray evidence which seems to me to suggest a benign lesion rather than a malignant one. If it is malignant I suppose it is probably a carcinoma. It would seem to be more likely that this lesion on the lesser curvature is a benign ulcer.

DR HORATIO ROGERS I think that the dramatic change in the character of the symptoms and the failure to respond to medication, which had hitherto been successful, are points in favor of the lesion's being malignant

#### PREOPERATIVE DIAGNOSIS

Benign gastric ulcer

#### DR BARTLETT'S DIAGNOSIS

Benign gastric ulcer

#### ANATOMICAL DIAGNOSIS

Colloid carcinoma of stomach, with peptic ulceration

#### PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY The patient was operated on by Dr Arthur W Allen, with a preoperative diagnosis of a benign ulcer. He found a large penetrating ulcer on the lesser curvature. He also found a very definite old ulcer in the duodenum with adhesions and marked scarring around it. He excised the stomach ulcer. Grossly it was almost the same shape as the lesion that you saw in the x-ray film. There was a very deeply penetrating rather narrow crater. Microscopically the mucous membrane on either side looks at first glance to be quite normal, but when one focuses down with high power on the undermined edges one finds that the underlying tissue is full of small, signet-ring cells filled with mucin, and there is

no question that it is malignant. The infiltration extends a considerable distance on each side of the ulcer, in fact I am doubtful whether the resection was extensive enough to have removed the growth.

The question comes up again as to whether this represents cancer developing in a chronic ulcer or is a primary carcinoma with a secondary peptic ulcer in the center of the lesion. I do not believe in this particular case it is possible to reach an absolute decision, but the base of this ulcer does not look extremely chronic. It is consistent with a lesion of a few months' duration but not, I should say, with one of twenty years' duration, and we have definite proof from the surgical exploration that he had an old duodenal ulcer. I am inclined to think he had a duodenal ulcer for twenty-five years and developed cancer of the stomach a few months before he came to operation. I do not believe there is any possible way in which the preoperative diagnosis could have been made, either clinically or by x-ray.

DR SCHATZKI How do you explain the marked scarring in the stomach, resulting in marked shortening of the lesser curvature? If it was a primary cancer we should not expect such changes in so short a time.

DR MALLORY This is a signet-ring, colloid carcinoma of the scirrhus type, which eventually produces linitis plastica. Fibrosis is a characteristic feature and characteristically contracts and stiffens the stomach wall.

## REPORTS ON MEDICAL PROGRESS

In this issue of the *Journal* a new series of "Reports on Medical Progress" begins. The object of a review of this sort is to inform the general practitioner in regard to the newer, approved methods in the diagnosis and treatment of disease, but the members of the editorial board are of the opinion that the majority of our former progress reports failed in their purpose. Some chiefly consisted of a listing of titles, with no critical evaluation of the papers by the author of the review. Others called attention to methods of diagnosis and treatment that were in the experimental stage. While it is true that such reviews have their place in medical literature, the busy physician does not have the time to refer to the original articles, nor is he able to separate "the wheat from the chaff" in subjects with which he is unfamiliar.

The new reports, which will appear weekly, are limited to approximately three thousand words. They do not represent meticulous reviews of the literature, but rather those particular aspects of each subject that, in the opinion of the reviewer, — who has been carefully selected, — are of proved value to the general practitioner in diagnosis and treatment. A few references are included for the use of those who wish to read extensively. In other words, the reviews represent what authoritative persons would say in a series of informal talks.

All but seven of the men who were originally asked to contribute to the series have agreed to do so, for this the *Journal* is duly grateful. Each review represents time and effort on the part of the reviewer that are generously contributed for the purpose of furthering postgraduate medical education. Any suggestions from our readers in regard to the value, form or subjects of these weekly reports will be received with appreciation and interest.

## THE LEGAL STATUS OF CONTRACEPTIVE ADVICE IN MASSACHUSETTS

For many years Massachusetts physicians have sought to protect the lives and health of their private patients by giving them contraceptive advice when, in their opinion, pregnancy was temporarily or permanently contraindicated. It became evident however that a far from negligible proportion of the women of Massachusetts — those who had no private physician and who belonged to the "out-patient" class — were forced either to deny themselves to their husbands or to risk their lives or health by becoming pregnant.

In 1931 an attempt was made to amend the law so that physicians might be exempt from its restrictions when, in their opinion, there was good evidence that pregnancy might be dangerous to the patient's life or health. This attempt failed.

In 1932, after being advised by a well-known law firm that the legal restrictions would in all likelihood not be construed as applying to physi-

cians in the bona fide practice of their profession, the Birth Control League of Massachusetts was instrumental in establishing the Mothers' Health Office in Brookline. The office was conducted by a qualified physician, under the supervision of a board of medical consultants, advice was given only to married, non-pregnant women whose physical or mental condition contraindicated pregnancy. For five years this office carried on without molestation, patients were referred by the leading hospitals of Boston, by private physicians and by social agencies. By 1937 similar offices had been opened in Boston, Fitchburg, New Bedford, Springfield, Worcester and Salem.

On June 3, 1937, the Salem office was visited by the police, confidential records were taken and the physician in charge, the nurse and two social workers were arrested on the charge that they "did sell, lend, give away, exhibit or offer to sell, lend or give away instruments and other articles and drugs and medicine for the prevention of conception." The attorney for the defense did not deny that the defendants had done these things, but contended that the prohibitions contained in the statutes did not apply to physicians and to those working under their direction when contraceptive advice was given for the purpose of protecting health and saving life.

Judge Sears, before whom the case was tried, stated in effect that he had no doubt the defendants had been actuated by worthy motives, but that it was not within his power to interpret the law contrary to its obvious meaning. He therefore found all the defendants guilty. This decision was sustained in the Superior Court and was then appealed to the Supreme Judicial Court of the Commonwealth. Chief Justice Rugg, who handed down the decision, said "We think that such an exception cannot be read into our statute by judicial interpretation. The relief, here urged, must be sought from the law-making department and not from the judicial department of government."

The case was then appealed to the United States Supreme Court on the ground that the Massachusetts statutes violated the first article of the State Constitution of Massachusetts and the fourteenth

amendment of the Constitution of the United States. On October 10, 1938, the Supreme Court refused to review the case on the technical ground that there was a "want of a substantial federal question."

These decisions give to Massachusetts the distinction of being the only state in the Union in which the existing laws have interfered with the medical advice that a physician is entitled to give to his patients. A number of physicians in this state appear not to realize their significance. These rulings affect not alone marital happiness, the health of women and the well-being of children, but even more fundamentally, they strike at the right of the individual physician to use his knowledge for the benefit of his patients.

Possibly the existing statutes will be reinterpreted in the light of new test cases that place the basic issue more clearly and directly before the courts. Failing that, the law must be amended. In any event, the public must become better informed regarding the facts involved. Too many people believe that birth control predicates abortion, that the avoidance of dangerous pregnancy is merely a matter of self-control. The dissemination of contraceptive information belongs by right to the medical profession, it should not be bootlegged as it is now, nor have to be given by physicians in defiance of the law.

#### PLACENTA ACCRETA

Mrs. M. B., a thirty-four-year-old primipara, started to bleed February 4, 1936, three days after delivery.

The family history was essentially negative. The patient had had a ruptured appendix as a child, and her tonsils were removed twice. She had had the usual childhood diseases, including diphtheria. Catamenia began at thirteen, were

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

regular with a twenty-eight-day cycle, lasted four days and were unaccompanied by pain. Her last period was April 6, 1935, which made her expected date of confinement January 13. She had had no complications during her pregnancy, and a blood Wassermann test was negative.

After a normal, primiparous labor lasting about five hours and a half, she was delivered by simple forceps because of an unusual amount of bright show. This was subsequently found to be due to a partial separation of the placenta, as there was a clot adherent to the separated area. The placenta was delivered normally and was apparently intact. There was no unusual bleeding after delivery.

Three days later she began to bleed profusely, the hemorrhage was so marked that within an hour her blood pressure had gone down to 70 systolic. Five hundred cubic centimeters of glucose and 500 cc of her husband's blood were given before any attempt was made to ascertain the cause of the bleeding. On examination there was no bleeding from the cervix. Exploration of the uterus revealed a tongue-like piece of tissue hanging down from the posterior wall up toward the right horn. Part of this was removed by forceps and some was obtained by curet, the uterus was packed with an iodine strip. At the end of the operation her pulse rate was 100 and her color was satisfactory. No laboratory work was done on the patient's blood until two days later. At that time the hemoglobin was 35 per cent, the white-blood-cell count 19,400, and the red-blood-cell count 1,740,000.

The next day, February 7, she began to bleed again, but the hemorrhage was not profuse. However, since her blood pressure fell from 120 to 100 systolic during the next hour, hysterectomy was decided on. Transfusion was deferred until the end of the operation. No blood examination was made until the following day when the hemoglobin was 45 per cent, the white-blood-cell count 86,000, and the red-blood-cell count 2,820,000. She made a satisfactory convalescence, although she ran an elevated temperature for five days after operation.

The subsequent laboratory work on her blood was as follows: February 9, white-blood-cell count 53,000, February 10, hemoglobin 45 per cent, white-blood-cell count 18,800, red-blood-cell count 2,100,000, February 15, hemoglobin 50 per cent, white-blood-cell count 20,700, red-blood-cell count 2,860,000, February 21, hemoglobin 55 per cent, white-blood-cell count 13,500, red-blood-cell count, 2,900,000, February 26, hemoglobin 65 per cent, white-blood-cell count 8,800, red-blood-cell count 3,620,000.

The following is the pathological report.

The specimen consists of a postpartum uterus, fixed in formalin, which has been opened anteriorly by a midline vertical incision. The specimen measures 12 cm in width, 12 cm in height and 6.5 cm. in thickness. The myometrium is of normal color and consistency for a formalin fixed postpartum uterus. The myometrium measures 2.5 cm in thickness. The placental site is at the fundus, mostly posteriorly. There are irregular, small masses of placental tissue, the largest of which is 2 cm in diameter and is located in the region of the right cornu. There are thrombosed sinusoids in the immediate neighborhood of the placental site, which in the fixed condition and the contracted state of the uterus measures approximately 5 cm in diameter. The rest of the lining of the uterus, composed of decidua vera, is dirty greenish grey and of irregular contour. On gross examination, the findings

Figure 1 Section through Placental Site ( $\times 17$ )

suggest those of placenta accreta, particularly in view of the fact that the spongy decidual reaction appears to be very slight in the right cornu. Multiple vertical incisions in the uterine wall reveal no other areas of adherent placental tissue. On microscopical examination, a section taken from the region of the right cornua and one somewhat removed from there, both show adherent placental tissue (Fig 1).

Diagnosis: postpartum uterus, with evidence of retained placental tissue (placenta accreta).

**Comment** Postpartum hemorrhage that occurs a few hours or longer after delivery must always be due to one of two conditions: the slipping of sutures placed in a torn cervix or repaired perineum, or uterine bleeding due to retained placental tissue, possibly an accreta. The diagnosis cannot be made except by examination. In this

case there was no bleeding from the episiotomy wound and the cervix had not been sutured at the time of delivery, hence the bleeding must have come from the inside of the uterus

The commonest cause of postpartum uterine bleeding is a cotyledon or a succenturiate placenta that is adherent and not expelled at the time of delivery, but a placenta accreta is sometimes found to be responsible. The diagnosis rests on intrauterine investigation. In this case examination proved that retained placental tissue was the cause of the bleeding, and since this could not be removed either by the finger or by instrumentation, it was inferred that a partial accreta existed. The packing of the uterus was done to control subsequent bleeding and also in the hope that this piece of placental tissue might be normally extruded. Subsequent hemorrhage, however, made operation necessary, and hysterectomy seemed to be the only means of adequately controlling the bleeding and of removing the cause at the same time. It was unfortunate that the uterus had to be sacrificed in a woman only thirty-four years of age, but pathological examination proved this to have been the intelligent procedure.

#### MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning January 9

##### BRISTOL SOUTH (New Bedford Section)

Friday, January 13, at 4 00 p. m., at the St. Luke's Hospital, New Bedford. Subject—Sepsis. Instructor—A. Gordon Gauld. Robert H. Goodwin, *Chairman*

##### WORCESTER

Tuesday, January 10, at 8 30 p. m., in the Nurses Home of the Milford Hospital, Milford. Subject—The Control and Treatment of Respiratory Infections. (This is to include the serological treatment of pneumonia in infants and children.) Instructor—Charles F. McKhann. Joseph Ashkins, *Chairman*

#### A MEANS OF IMPROVING THE DISTRIBUTION OF MEDICAL CARE IN MASSACHUSETTS\*

We have of late been hearing much to the effect that the executive branch of our federal government seems committed to a policy which would greatly enlarge government's participation in the care of the sick. This is food for deep and earnest thought, particularly as some of the changes contemplated call for a radical and revolutionary departure from the present control of the distribution of medical care.

We may ask ourselves two questions as touching on the wisdom of these new proposals. First, Is the present

set up of medical care so basically wrong and so outdistanced by the present social order that even its modification will not suffice? Secondly, Is there a middle road which, while preserving all that is good in American medicine, will at the same time take due notice of its shortcomings and voluntarily seek the means of their correction? The great majority of the people, who have thought of this matter at all, earnestly desire and hope for the accomplishment of this latter. May I present to you today a program which bids fair to bring about this very desirable end?

This program is founded on the studies of the Massachusetts Medical Society as to the present medical needs of the people of our state. There has come from these studies the firm conviction that, whatever may be the condition in certain other parts of our country, there is today in Massachusetts no serious lack of medical facilities. The problem has almost entirely to do with such improvement in the distribution of our present facilities as will make them more readily available to all. This implies, in the first instance, a program of public education in the value of good health. This program should start with the child and continue as a very important part of his school curriculum. If further emphasis is needed as to the importance of this latter, let me point out that our studies showed that, of those inadequately cared for in Massachusetts, nearly half were poorly cared for because of their own indifference. It appears that it is not enough merely to offer free medical care to those who cannot afford to pay for it. An appetite for good health must be created. A bounteous meal means nothing to the man who has no desire to eat.

This matter of educating boys and girls in the value of good health and in the means of preserving it does not involve the setting up of any new machinery. Rather does it seek to place greater emphasis on, and to promote a greater utilization of, machinery already existent. Massachusetts school systems have, for approximately three decades, provided for the medical inspection of the children in their keeping. The greater utilization of this machinery along the lines of educating these children in the value of good health is an opportunity for closer co-operation between school authorities and their medical personnel.

The medical needs of the indigent should be supported out of tax funds just as the food, clothing and housing needs are now provided. The indigent patient should be treated as an individual patient by the doctor of his own choice. The payment for such services should be by agreement between local welfare authorities and local medical societies. I know full well that the responsibility for the medical care of the poor is the traditional role of the doctor. In this crisis through which we are passing however, this load lays a heavy burden on a profession which is already supplying its proportional share of direct and indirect tax funds. This double system of taxation has for many about reached the point of exhaustion. This responsibility belongs to the whole people, and not to any particular group.

The principle of insurance against the unpredictable hazards of life should be utilized by the low income and moderate income groups as a means of financing the cost of their medical care. These groups represent the great bulk of our population. The practice of doctors to scale down their charges to meet these lesser pocketbooks has, we are told, not met the whole problem. Neither is it enough to say that those with such incomes should budget in the ordinary way to meet the costs of sickness. Many of such incomes are so small as to make the ordinary type of budgeting impossible. Again, if we are to be practical

\* Green Lights to Health broadcast given by Dr. Michael A. Tighe on Wednesday, December 14 and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

in this matter we must admit that the number of people who do and who will budget to care for such an unpredictable thing as sickness is very small indeed. Rarely does the individual anticipate being ill. Illness is for the other fellow and not for him.

Hence, another type of budgeting to meet the costs of illness becomes necessary—a painless type of budgeting, a type of budgeting which, while recognizing the demands of pressing and immediate needs and the lure of the many useful things which go to make up American life, still may set aside weekly, in an insurance system, the price of a movie as the premium to pay for adequate medical care.

Part of the machinery for bringing this about has already been set up. The Associated Hospital Service Corporation began its operations a little over a year ago. This is a non-profit organization authorized under a special act of the Massachusetts legislature. The organization is already meeting the problem of hospital costs for many thousands of our people. The selection of the policyholder under this contract has been careful—too careful is the criticism of many. It must be remembered, however, that this was virgin soil and that the interests of the policyholder must be protected against any contingency. An examination of the financial reports of this Massachusetts corporation and of others, notably that of New York, shows how rapidly a surplus against any contingency is being built. This having been accomplished there are three ways in which such an organization may expand: first, by lessening the premiums—the premiums are, however, already within the reach of all; second, by increasing the service—the service is already adequate, with many comforts thrown in; third, by lessening some of the restrictions which are at present thrown around its membership. This last would seem to be the way of expansion for an organization whose whole purpose is to supply in a painless way the hospital needs of the people.

The newer part of this program calls, in part, for the immediate creation of an insurance system which, for a small premium, will meet the policyholder's doctor's bill. This latter system might very well be set up on much the same basis as that of the Associated Hospital Service Corporation. It should, however, be a distinct organization. It should preferably be non-profit, with the policyholder getting the benefit of whatever earnings the organization shows above and beyond that surplus necessary to maintain its financial soundness.

And finally the program demands the formation of a health council in each community. This council should be made up of all those agencies having to do with the distribution of medical care—hospitals, nurses, doctors, welfare and health organizations and social service units. This type of committee would be in the best position to study and to know local needs, and the manner and means by which the rest of the program can be made to fit those needs.

This program has the endorsement of the Massachusetts Medical Society, the American Medical Association, the American, Catholic, and Protestant hospital associations and their subsidiary affiliates.

MR. CHARLES E. GALLAGHER\* This is a splendid program, Dr. Tighe. I like its simplicity, and its comprehensive nature. Your emphasis on health education is well placed. None of us laymen know enough, or think enough, of the means of preserving our health. I quite agree with you that this type of education should start in the impressionable days of childhood.

I like your thought that the poor man should be cared for as an individual by the doctor of his own choice. This

is the kind of medical care I want, and I can desire no less for him.

That part of the program which provides the means by which those with moderate incomes may easily finance their medical needs is bound to have great public support. The alacrity with which the people have accepted the plan of the Associated Hospital Service Corporation and the practical way in which it is working out are, in my opinion, a fair index of how this second part of the program—indemnity against doctors' bills—will be received.

The formation of community health councils is a splendid idea. I can well understand that the problem of the distribution of medical care may vary as the community varies. Who is in a more favored position to know the specific medical needs of a particular community than those who are actually engaged in the work of distribution?

I like the program as a whole because it is an attempt to assist the average man to help himself. I like it because it involves a minimal administrative cost—a guarantee that most of the dollar spent will accrue to the interest of the person spending it. I like it because it maintains the intimate relation between doctor and patient, with the initiative of that doctor to excel encouraged rather than discouraged. I cannot help but contrast a program of this character with the compulsory sickness-insurance plan as proposed by certain governmental agencies. I see in this latter an inevitably high administrative cost and the creation of an enormous political bureaucracy. For my part, I should rather that politics and political methods be kept out of the care of the sick.

## NOTICES

### REMOVAL

HENRY BORUCHOFF, M.D., announces the removal of his office to 192 Bay State Road, Boston.

AARON KAUFMAN, M.D., announces the removal of his office to 395 Commonwealth Avenue, Boston.

### TUMOR CLINIC, BOSTON DISPENSARY

Each Tuesday and Friday morning, 10:00 to 12:30, there is a meeting of the Tumor Clinic of the Boston Dispensary, a unit of the New England Medical Center. Neoplasms of various sorts are seen and discussed, and when there is an indication, are treated with radium or high voltage x-ray. Physicians are invited to visit this clinic. They may bring patients for aid in diagnosis or may refer patients to the clinic following which a report will be returned to the referring physician. A limited number of beds are available for diagnostic study and for treatment.

### MEDICAL CLINIC AT THE PETER BENT BRIGHAM HOSPITAL

At 3:30 p.m. on Thursday, January 12, in the Amphitheater of the Peter Bent Brigham Hospital, Dr. Henry A. Christian, Hersey Professor of the Theory and Practice of Physics, Harvard Medical School and physician in chief, Peter Bent Brigham Hospital, will give a medical clinic. Practitioners and medical students are cordially invited to attend.

### BOSTON CITY HOSPITAL

The monthly clinicopathological conference will be held at the Boston City Hospital on Wednesday, January 11, at 12 o'clock noon, in the Pathological Amphitheater.

JOSEPH E. HALLISEY, M.D. Secretary  
Medical Staff

## HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Tuesday, January 10, at 8 15 p m., in the Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance) Dr E Stanley Emery will preside.

## PROGRAM

Presentation of cases

The Role of Intubation in the Study and Treatment of the Small Intestine. Dr W Osler Abbott.

Medical students and physicians are cordially invited to attend.

ROBERT ZOLLINGER, M.D., *Secretary*

## BOSTON MEDICAL HISTORY CLUB

There will be a meeting of the Boston Medical History Club at the Boston Medical Library, 8 Fenway, Boston, Monday, January 9, at 8 15 p m.

Dr Edwin B Dunphy will talk on "The Development of Our Knowledge of the Diseases of the Eye."

Members of the medical profession and other interested persons are cordially invited to attend.

PAUL D WHITE, M.D., *President*,  
BENJAMIN SPECTOR, M.D., *Secretary*

## SOUTH END MEDICAL CLUB

The next meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, January 17, at 12 o'clock noon.

Dr Thomas H. Ham will speak on "Laboratory Procedures in Hospital Practice."

Physicians are cordially invited to attend

JOHN B HALL, M.D., *Secretary*

## SOCIETY MEETINGS AND CONFERENCES

## CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, JANUARY 9

## MONDAY JANUARY 9

\*4 p m Physicians and medical students are cordially invited to attend a clinic presented by the medical surgical and orthopedic services of the Infants and Children's hospitals in the amphitheater of the Children's Hospital

\*8 15 p m Boston Medical History Club Boston Medical Library

## TUESDAY JANUARY 10

\*9 10 a m Joseph H Pratt Diagnostic Hospital Clinical Value of Male Hormone Assays Dr C H Lawrence and Dr A C Moullyn

\*10 a m 12 30 p m Tumor clinic Boston Dispensary

\*8 15 p m Harvard Medical Society Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance)

## WEDNESDAY JANUARY 11

Eastern Section of the American Laryngological Rhinological and Otolological societies in conjunction with the New England Oto-Laryngological Society Massachusetts General Hospital

\*9 10 a m Joseph H Pratt Diagnostic Hospital Hospital case presentation Dr S J Thannhauser

\*12 m Clinicopathological conference Children's Hospital amphitheater

12 m Boston City Hospital Monthly clinicopathological conference pathological amphitheater

## THURSDAY JANUARY 12

8 30-9 30 a m Exchange visit Surgical and Orthopedic Staffs of the Peter Bent Brigham and Children's hospitals held this week at the Children's Hospital Surgical

9 10 a m Joseph H Pratt Diagnostic Hospital An Unknown Hereditary Dyscrasia of the Blood Dr H G Brugsch

\*3 30 p m Medical clinic at the Peter Bent Brigham Hospital

## FRIDAY JANUARY 13

9 10 a m Joseph H Pratt Diagnostic Hospital The Diagnostic Importance of Pain Referred from the Digestive Tract Dr C M Jones

\*10 a m 12 30 p m Tumor clinic Boston Dispensary

## SATURDAY JANUARY 14

\*9 10 a m Joseph H Pratt Diagnostic Hospital Hospital case presentation Dr S J Thannhauser

\*10 a m 12 m Staff rounds at the Peter Bent Brigham Hospital Conducted by Dr Henry A Christian

## SUNDAY JANUARY 15

4 p m Illustrated public health lecture Faulkner Hospital auditorium The Surgical Treatment of Stomach and Duodenal Ulcers Dr Edward L Young Jr

4 p m Free public lecture, Harvard Medical School amphitheater of Building D The Skin What it does and the care it needs." Dr C Guy Lane

## A NATIONAL HEALTH PROGRAM\*

WARREN F. DRAPER, M.D.†

WASHINGTON, DISTRICT OF COLUMBIA

YOU have come here, I believe, to find out what those who have been considering a national program of health have in mind, how it will work and what the results will be. I shall try to give you as much of this information as has been developed and can be supplied in a period of thirty minutes, and I shall make it as simple and direct as possible.

I assume that all of you know that proposals for a national health program have been made by an interdepartmental committee appointed by the President consisting of officials from the major federal departments most closely concerned with the provisions of the Social Security Act. A technical subcommittee on medical care was set up, and it was the report of the latter that formed the basis of the National Health Conference, which has stimulated nation-wide interest and discussion.

The purpose of the committee was to appraise the state of the nation's health and to arrive at conclusions as to what could and should be done to improve it. This was a logical course of action because in addition to the humanitarian elements involved, illness and death cost taxpayers money. The social security laws provide pensions for dependent children, some of whom may be made fatherless by the death of the bread-winner from tuberculosis or made motherless by death in childbirth. Pensions are paid for the blind. It is certainly not good business to pay pensions to persons made unemployable, dependent and destitute because of preventable illness without trying to do something to prevent the illness and restore the sick to health. This basic relation between health and economic welfare was recognized in the Social Security Act already in operation, and an annual appropriation of \$12,000,000 for the United States Public Health Service and the Children's Bureau was authorized to aid the states in their efforts to improve the public health. A beginning has

been made and commendable work is being done, but it will require a much greater effort to do what we know how to do along these lines.

We may take deep satisfaction in the brilliant advances that have been made in scientific knowledge and the practice of preventive and curative medicine. Our general death rate is the lowest on record. It has been reduced from 176 per thousand in 1900 to 11.5 in 1936, which represents a saving of about three quarters of a million lives in 1936 alone. During the same period, twelve years were added to the average expectation of life at birth. The saving, however, has been chiefly in the years of childhood and early adult life, when the preventable diseases are most frequent. Mortality in the higher ages has not in general been declining, and those who reach the age of fifty years or over have little reason to believe that they will live for more than a fraction of a year longer than if they had reached that age in 1900. In some of the important diseases of adult life the death rate has been increasing—in cancer, for example, and in diseases of the heart, blood vessels and kidneys.

Fine though the record has been, there are serious problems of health and medical care that yet remain to be solved, and new ones are constantly arising. It is with these and the possibilities of future accomplishments that we have to deal if unnecessary suffering and wastage of human life and resources are to be averted. Let us, then, review some of the findings that have been made, considering first those conditions within the field of public health for which known remedies are at hand.

### EXPANSION OF PUBLIC-HEALTH AND MATERNAL AND CHILD-HEALTH SERVICES

*Venereal Disease* The venereal diseases of course constitute our greatest health problem. Of syphilis especially much information has been received

\*An address delivered at the New England Postgraduate Assembly, Cambridge, November 15, 1938.

†Assistant surgeon general, United States Public Health Service.

of late I shall recall only a few of the more important facts

A total of 518,000 persons newly infected with syphilis seek treatment each year. More than 1,000,000 seek treatment for gonorrhea. There are probably an equal number of sufferers from these diseases who do not seek treatment. Some 60,000 babies with syphilis are born each year. There are 40,000 deaths each year from syphilitic disease of the blood vessels and the heart, 80 per cent of which could be prevented by adequate treatment in the early stages. The cost of maintaining persons blinded by preventable syphilis is \$10,000,000 a year. About 10 per cent of the patients in our hospitals for the insane are there because of syphilis. The annual cost of their care is about \$31,500,000. Surgeon General Parran has stated that syphilis can be brought down to a small fraction of its present prevalence in a decade and essentially wiped out within a generation if the knowledge already available is effectively applied.

**Pneumonia** Pneumonia stands third on the list of the causes of death. An average of 96,500 persons died from this disease each year from 1930 to 1935. The death rate is highest among infants and children of the pre-school ages, and among persons in late-middle and old age. Nearly 600,000 persons are disabled from it annually. Current experiments in the mass prevention of pneumonia by protective inoculation give great promise of success. In serum treatment and other methods the means are at hand to reduce greatly the mortality of and disability from the disease, even after it has been contracted. However, the laboratory facilities and the serum necessary for this expensive life-saving treatment are available in only a very few places to those who are unable to pay the cost.

**Cancer** Cancer is second on the list of the causes of death, and claimed 143,000 victims in 1936. There are probably 400,000 persons in the United States today suffering from cancer. Under present conditions it is estimated that one of every eight persons who reaches the age of forty-five will die of cancer. Yet leading authorities have estimated that as many as 40,000 of these lives might be saved each year if all the patients received the benefits of modern methods of treatment, and if opportunity were provided for the diagnosis of a larger number of cases in the early stages.

**Tuberculosis** There are still about 70,000 deaths from tuberculosis each year. Forty thousand of these occur among adults between the ages of forty and forty-five. Those qualified to judge are of the opinion that the deaths can be reduced by 50

per cent through the health supervision of workers in occupations predisposing to the disease, through the detection of incipient cases and through the provision of adequate medical and institutional care in the early stages. Most cases are discovered too late for effective treatment, and far too many reach sanatoriums when the disease has advanced too far for a hopeful outcome.

**Diabetes** There are probably between 400,000 and 500,000 persons suffering from diabetes, with 30,000 deaths each year. If insulin can be made available to all those who need it, and properly administered with the other treatment indicated, deaths can be reduced and life prolonged.

**Maternal and Infant Mortality** Today there is a great and unnecessary waste of maternal and infant life. Physicians after careful evaluation of the causes responsible for the deaths of mothers report that at least half the 14,000 deaths of women which occur each year from causes connected with pregnancy and childbirth can be prevented. About 75,000 infants are stillborn, and almost an equal number die in the first month of life. These deaths are due in large measure to lack of adequate care of the mother during pregnancy and at delivery and of mother and infant during the postnatal period.

Experience has shown that piecemeal effort—a prenatal clinic or a public-health nurse here and there—is not sufficient to reduce this wastage in human lives. What is needed is for every expectant mother to be under the supervision of a good physician during the prenatal period, and to receive proper service at delivery and adequate medical and nursing attention for herself and her baby thereafter. It is the proposal of the committee that the funds to make this possible be made available to state and local agencies.

**Mental Disease** An estimated total of 500,000 persons are in hospitals for mental disease. The mentally diseased and defective demand more than twice the volume of hospital and institutional care required of all other diseases combined. In 1934 all but 2 per cent of patients in hospitals for mental disease were in public institutions, approximately \$150,000,000 is expended annually for their care. Known methods are far from being fully utilized for the prevention, treatment and supervision of the mentally diseased and deficient.

These are but a few examples, briefly presented, of the public-health problems with which we are confronted, but perhaps they will suffice to show the need for doing something more than has been done. It is possible by applying the knowledge

of public health now available to cut down greatly the economic losses these and other diseases entail. The plan which the committee recommends is in substance as follows:

*A* The development of state and local health organizations to a degree that will enable them to apply more generally and effectively public-health measures for the prevention of disease and the promotion of health.

In view of the excellent beginning already made in carrying out health activities under the provisions of the Social Security Act, it is recommended that federal participation in state and local health services be extended through additional grants-in-aid to the states. Increasing federal participation and leadership should promote the inauguration and expansion of fundamental and accepted health services, and the extension of newly developed services under state and local operation and control. Special effort should be directed toward those diseases which are important causes of sickness and death and against which we already have effective measures of proved value: tuberculosis, venereal diseases, pneumonia, cancer, malaria, mental diseases and occupational diseases.

*B* The expansion of the work already carried on under the provisions of the Social Security Act for health services to mothers, children and crippled children.

It may be possible to save the lives of 70,000 mothers and babies each year if means are made available. There are 90,000 deaths a year of children under fifteen. Note that the work is done through the state and local health agencies of the several states in accordance with the laws of each.

#### MEDICAL CARE FOR THE MEDICALLY NEEDY

The need for medical care of persons on relief and in families with very low incomes is completely recognized by the medical profession, by public-health and welfare authorities and by others. While death rates are higher and sickness more frequent and severe among the poor than among families in comfortable circumstances, the poor receive less medical care than the well-to-do. There is not a state in the nation, and scarcely a county or city, that has not been confronted with this critical problem. Yet the present system of public medical care has failed to meet this situation.

It is estimated that 40,000,000 persons—almost one third of our population—are today in families with incomes of less than \$800. Half this group are dependent on public funds for food and shelter. The other half—the so-called self-supporting families—can provide a minimum of food, clothing and shelter for themselves, but can-

not meet their sickness costs. A family in this latter group may go along for months without applying for relief. Then the bread-winner becomes sick, and income, precarious as it is, stops. The family is on relief. Or again, a mother contributing to the support of the family may have to give up her job to care for a sick child or husband, and so the family goes on relief. A large proportion of such needy people live in small cities or rural areas in which there are few hospitals, doctors and nurses. This is a major obstacle to their efforts to obtain adequate medical care.

Local governments have proved unequal to the solution of such problems without assistance. It is the proposal of the committee, therefore, that state programs aided by the federal government be developed as the only adequate solution for the needs for medical care of this large group of the population. Public funds in addition to those now expended are necessary to pay for physicians' fees, drugs and appliances, hospitalization and nursing care and essential dentistry. The committee recommends that the programs be organized on a state and local basis, with the full cooperation of the medical profession and of public and private hospitals and clinics, health departments and welfare agencies. No uniform program is proposed to meet the varying needs of the states. Indeed, the proposal for medical care of the poor is founded on the belief that, given necessary financial and technical aid, every state will be able to work out a satisfactory way whereby its sick poor will receive an approved standard of medical care, the costs of which, including doctor's services, are paid from public funds.

#### EXPANSION OF HOSPITAL FACILITIES

The development of any program designed to provide medical services to meet the needs of large groups of people involves a consideration of existing hospital facilities. The second recommendation of the committee therefore relates to the expansion of hospital facilities. It embraces a plan for providing essential hospital beds and facilities with such geographic distribution that they will be within reasonable distance and at reasonable cost so that the great majority of our people who need them can use them. It is proposed to add 360,000 beds to the million now found in registered general hospitals, tuberculosis sanatoriums and mental institutions. In addition, the committee proposes the construction and equipment of at least 500 diagnostic centers in remote areas where it would be impracticable to construct hospitals. These could also serve as headquarters for local health departments, thus co-ordinating the health services of the community. Through these

centers, as well as through the proposed expansion of hospital facilities, physicians hitherto handicapped by lack of adequate diagnostic equipment and laboratory services would be able to render better service to their patients

It is not planned to build a new hospital in every county in the United States. The committee simply proposes to aid the states in increasing the number of free and low-cost beds in general hospitals in communities where they are needed, and to relieve the already overcrowded conditions in tax-supported institutions for the care of the tuberculous and the mentally ill. This may be done either by building new institutions or by adding to approved hospitals. In its program for the expansion of hospital facilities, the committee considers the country as a whole with its varying social, economic and geographic conditions. The estimate of 360,000 additional beds and 500 diagnostic centers, with temporary maintenance grants for the support of the new beds, represents a measure of need on a national basis which must be subdivided to ascertain local requirements.

#### GENERAL PROGRAM OF MEDICAL CARE

The fourth major problem to which the committee has given consideration relates to the financial burdens and the economic insecurity which sickness creates for self-supporting persons. I do not believe that anyone knows all the answers to the problems of general medical care, nor does the committee assume this position. Nevertheless, sufficient experience has been gained in other countries and in the operation of many plans now under way in different parts of the United States to warrant planning for a more even distribution of the costs of medical care in this group.

No one can say whether your family or mine will get through the next year without a catastrophic illness. Self-supporting families can ordinarily meet the costs of minor sickness, but often they are unable to cope with a prolonged, serious illness. For the vast majority of our people, such a catastrophe often spells an insupportable burden of debt, even of serious curtailment of income and of financial disaster. The committee recommends that federal aid be given the states so that they may develop plans for distributing this unpredictable and disastrous burden of illness in families in moderate circumstances. Two ways—or a combination of the two—are suggested. The first is to finance medical care for the entire population through a general tax. The second relates to self-supporting families only, and involves the application of the insurance principle. A scheme of compulsory health insurance, aided in part by the federal government, would require

contributions by the insured. Since it would be difficult if not impossible to apply the insurance principle to a numerous group of the population, namely agricultural workers, domestic labor and of course the unemployed, it might be necessary for some states to adopt a combination of these two methods.

It should be borne in mind that the committee at no point in this program suggests a national compulsory health-insurance plan or any mechanism for the rendering of medical care which would call for federal or state regimentation of medical practice. The road is left open to every state and every community to work out a satisfactory way by which medical care may be purchased without hardship. Federal participation would be confined to financial assistance and technical aid in developing the program.

#### INSURANCE AGAINST LOSS OF WAGES DURING SICKNESS

The fifth recommendation of the committee contemplates a plan of compensation for loss of wages because of sickness. The principle of this program is written into the law of virtually every state in the Union in workmen's compensation provisions. It is proposed that the federal government take the leadership in extending this principle to cover loss of wages resulting from general illness, as well as sickness resulting from employment. In view of the fact that not only the costs of medical care but the loss of income during disability is a principal factor in dependency—in good times and in bad—this proposal is both reasonable and sound.

#### COSTS OF THE PROPOSED PROGRAM

What will this vast program cost, and who will pay for it? It should be stated that the committee made no estimates for the costs of the last two recommendations, since these proposals deal primarily with suggestions for the redistribution of over-all expenditures now being made. The estimated costs of the first three proposals are governed by the principle of effective, comprehensive, long-range planning. A gradual development of the needed facilities and services over a ten-year period is contemplated. Effectively to establish adequate public-health service, maternal and child-welfare programs, medical care of the needy and expansion of hospital facilities, a maximum estimate of \$850,000,000 annually in funds from federal, state and local governments was made. Of this sum the federal government would pay on the average about 50 per cent.

Estimates for preliminary stages of the program were made for certain of the proposed activities, as

*Recommendation I-A* (public health) For the first year, \$20,000,000 from federal, state and local sources, with gradual increases to a possible maximum of \$200,000,000 by the beginning of the seventh year

*Recommendation I-B* (maternal and child health) For maternity and infancy, during the first year, \$9,000,000, with gradual increases to \$50,000,000 in the fifth year, and to the full amount, \$95,000,000, in not less than ten years. For medical care of children, during the first year, \$6,000,000, \$30,000,000 by the fifth year, and not less than \$60,000,000 by the tenth year, provided that Recommendations II and III are not in full operation at that time.

*Recommendation II* (hospital facilities) The total over all cost is estimated at \$1,104,500,000 for construction, plus \$177,000,000 in federal grants for temporary maintenance, or an average annual expenditure of about \$146,000,000 for ten years

*Recommendation III* (medical care for the medically needy) For the first year, \$50,000,000, by the fifth year, \$150,000,000, by the tenth year, \$400,000,000

Thus, in the first year it is estimated that approximately \$150,000,000 would suffice to launch sound, well-planned programs in these directions

Federal participation would amount to 50 per cent of the total expenditure, with the exception of temporary maintenance grants for hospital facilities which would be borne in whole by the federal government

\* \* \*

Our experience with the administration of the

public-health provisions of the Social Security Act has shown the effectiveness of federal and state co-operation in the development of sound programs of service and health conservation. Plans for the work to be accomplished are initiated in the state health departments. Administration and control of the activities carried on in the states remain in the hands of state and local authorities. The function of the federal government is to level the inequalities in financial resources in the states, and to provide the technical and consultant leadership essential in a well-co-ordinated national attack on preventable sickness and death.

These principles are suitable for immediate application in a far-reaching and comprehensive program for the health protection and medical care of our people. Indeed, it is suggested that the administrative procedures worked out by the states with the federal government in the development of the health provisions of the social-security program be used as a guide for future expansion.

The committee confidently expects from such a program a generous return on the investment. The question, from the business standpoint, is not, Can we afford a national health program of sufficient scope and extent to meet the needs, but rather, Can we afford not to do all that can be done to reduce needless sickness and death?

## THE CHANGING PRIVATE PRACTICE OF MEDICINE\*

ROGER I LEE, M.D.

BOSTON

IT is always a pleasure and privilege to listen to Warren Draper. He talks our language. It could hardly be otherwise since he received his formal education at Amherst and at the Harvard Medical School. But it is the man himself that catches our imagination and holds our admiration. To his formal education he brings humor, intelligence, sincerity and devotion. His experience, since his academic days, has been vast, and what he says is authoritative.

We shall all agree, I think, that in the last few years there has been a tumult and a turmoil about what seems to be designated at this moment as "socialized medicine." It appears to be the same thing that was once called the "cost of medical care," then later the "costs of medical care," and that eventually turned out to be none of these or even the "costs of sickness," which it might be argued was what was really meant. At this phase

the doctors contributed a phrase "medical economics" which was the worst term yet in its implications and possible interpretations. Perhaps socialized medicine is a good term. I do not know. But I do know that sociology is to many people the study of socialism. At this moment nearly everyone who has a pen or a voice has taken part in the excitement, and everyone has his theory. "State medicine," "compulsory health insurance," "adequate medical care for all," "medical care a right not a privilege" are phrases on the tip of everybody's tongue. Sociologists, reporters, economists, sob sisters, politicians, hospital superintendents, all want to reorganize the medical profession.

But the medical profession is not having a private row of its own. There is the Alberta Plan, the Thirty-Dollars-Every-Thursday, alias the Ham and-Eggs, Plan, and countless others. Everyone has his plan. It reminds one of the hurricane. Everyone wanted to tell his hurricane experi-

\*An address delivered at the New England Postgraduate Assembly, Cambridge, November 15, 1938.

ence We need a device like that of the sandwich man who on the bottom of his boards had printed 'I'll listen to your hurricane story for ten cents' I, for one, am prepared to believe that most of these plans are devised by honest, sincere people But experience leads to a certain cynicism For example, I recall that all the noted economists, with rare exceptions, if any, declared that the World War could only last two months or a few months at most I also recall that, with few or no exceptions, none of these economists predicted the so-called depression Yet it is a fact that the World War lasted over four years, and that there was a depression—somehow doctors survived both, which is more than can be said of many of our best businesses

At the National Health Conference held in Washington last summer, the comment of one man that "the plans were too simple to be reliable" merits careful consideration

I\* have elsewhere pointed out the obvious fact that rapid changes are taking place in medical practice Those changes are all in the direction of socialized medicine and state medicine I have watched in the hospital the birth and growth of social service I have watched the birth—in the same sense that Philadelphians always say that Benjamin Franklin was born in Philadelphia at the age of seventeen—of the United States Public Health Service and, again parenthetically, I am a member of its advisory council During long years of service on the Massachusetts Public Health Council, I have watched the growth of the state public-health activities At no time have I believed that close, friendly co-operation between medicine and public health is an impossibility But I have also watched the growth of the medical profession I point out now what is often forgotten, that the public-health movement was a legitimate and "planned" child of the medical profession and has always been fostered and nurtured by it And I also want to emphasize that the medical profession, essentially without assistance, corrected abuses and put education in medical schools on its present high plane True it is that certain governmental units, such as the Commonwealth of Massachusetts, have disgraceful licensing laws But that is a fault of the states, not of the profession Again, the extraordinarily favorable morbidity and mortality statistics in this country are due to the medical profession

Doubtless things have changed since the horse-and-buggy days, and even more since the doctor-saddlebag days, and yet more since the gold-headed-cane days Personally, I like to think of

the doctor using the gold head of the cane as something to put in his mouth because he knew so little in those days that any utterance of his might expose his ignorance But, there is ignorance in these days There were charlatans then as there are now Human nature has not changed (Indeed, it might be argued from some of the events in this troubled world that human nature is worse)

As I see it, the problems of medical practice are essentially only two that of the distribution of medical services and that of continuing the education of the practicing physician

So far, the bulk of the emphasis has been laid on distribution Formerly, the doctor took rich and poor in his stride One of the most successful general practitioners has told me that he never charged a servant, a minister, a doctor or a nurse And there were many others that he did not charge It is to the credit of the medical profession that the impetus to make professional charges for care of the indigent did not come from its ranks Yet it is an old custom The young doctor was the city or town physician or was paid a small sum yearly for work in the districts of the Boston Dispensary He did that to keep his hand in, if you will, but also to help out his budget,—accursed word of modern times,—just as he examined for insurance companies, and the like Nowadays there seems to be an agreement that the doctor should not carry, with out help or without some plan, the whole or nearly the whole of practice among the indigent And within the hospitals, the administrators see possibilities of balancing their budgets from reimbursements for the care of indigent patients

Your doctor of today must give much of his time and energy to keeping himself abreast of that swiftly running stream of medical progress The same friend to whom I referred earlier did his own social-service work, and he did it marvelously well But that too is largely given up by the practicing doctors This is an age of specialism Even if we grant, and I think we must, that specialism has gone too far, we must acknowledge that the public likes the idea of specialists (except the idea of paying for them) and that specialism has become a sort of legitimate showmanship that somehow gets by the committees on ethics and discipline Regardless of this, the practitioner who keeps himself in touch with medical advances is going to be a better, a more skilful doctor In most cases he is not going to be the family friend, except on the golf links or at the bridge table To be sure, this is a conservative view because many of our planners would have him a servant of the government And this, I fear, would result in many doctors becoming a

part of a great bureaucracy. But much more dismal than that picture is one of two great groups of practicing doctors, side by side and in competition. On the one hand, one might envisage the government, let us say the United States Public Health Service, developing and extending its practice of medicine. Of course, the beginnings would be small—the indigent, supposedly far-off areas, rural hospitals, and so forth. Is it likely or reasonable to suppose that these several hundred diagnostic clinics will be exclusively diagnostic? Who can differentiate precisely where diagnosis leaves off and treatment begins? Then let us remember the story of the camel and the tent. In my opinion such a situation would be indeed a calamity, but it is by no means fantastic.

I believe that if the doctors and the medical profession continue their consecration to the ideals and traditions which have brought forth such an abundant harvest in relation to the welfare of all the people, such changes as are necessary will be adopted now and in the future just as they have been in the past. Your 1938-model doctor hardly resembles his father, but medicine is still a glorious profession. It is not a trade, nor a political football and, please God, it will never be.

And in the end we will look on the glorious achievements of the past and present and say with justifiable pride, I shared, perhaps humbly, in some of these achievements. We have been through a war and through a depression, but we still have our profession.

264 Beacon Street.

## THE CHEMISTRY OF THE ANAEROBIC RECOVERY OF MUSCLE\*

OTTO MEYERHOF†

HEIDELBERG, GERMANY

IN THE course of the last fifteen years a great deal has been accomplished in the elucidation of the chemistry and thermodynamics of the processes which underlie muscular activity. Although the final goal, the understanding of the physical mechanisms of contraction and the interrelations of the various chemical processes, is as yet remote, the significance of the endothermic and exothermic reactions is gradually becoming clear.

In this report I shall discuss that portion of the process which is concerned with the events of the anaerobic-recovery phase of muscular contraction. Up to 1926, as is known, a study of muscle under anaerobic conditions revealed only the relation between muscular activity and the formation of lactic acid. Subsequently, two more chemical reactions were recognized which had both causal and temporal relations to the performance of work. One was the discovery that the "phosphagen" (Eggleton and Eggleton<sup>3</sup>) in muscle was creatinephosphate (Fiske and Subbarow<sup>5</sup>), which was capable both of decomposition into creatine and phosphate and of resynthesis into the original compound. The other was the discovery in 1929 of adenylypyrophosphate (adenosinetriphosphate), which can hydrolyze into adenylic acid (adenosinemonophosphate) and phosphate (Lohmann<sup>13, 15</sup> and Fiske and Subbarow<sup>6</sup>). These split products can then be resyn-

thesized, with the intermediary formation of adenosinediphosphate, into the original compound.

This hydrolysis of and esterification to adenosinetriphosphate constitutes a necessary step in the reaction that Embden had interpreted as the breakdown and synthesis of "lactacidogen" (the preformed hexosephosphate of muscle). Finally Lundsgaard,<sup>16-18</sup> in 1930, discovered that a muscle poisoned with iodoacetic acid could contract anaerobically for some time, entirely without the formation of lactic acid. Such important discoveries rendered the former concepts so inadequate that my friend A. V. Hill<sup>9</sup> in 1932 gave a series of lectures in America under the title "The Revolution in Muscle Physiology."

Such revolutionary periods are always fertile epochs. Although in the beginning some confusion of opinion may arise, and some doubting scientists may be ready to distrust and discard all the data, there gradually emerges a more clearly defined concept. This is especially true when the previous data are found to reinforce the new and permit the integration of the whole. The accumulation of new facts warrants such a formulation at present with regard to the processes of the anaerobic recovery of muscle.

The suspicion of contemporary scientists concerning the validity of our picture is based on two objections. (1) Do the chemical analyses of dead muscle, in which splitting and synthesis of the chemical compounds had been found, give a reliable picture of the events *in vivo*? Are they not

\*A lecture delivered before the Alpha Omega Society, Harvard Medical School, October 29, 1937.

†Formerly director of the Kaiser Wilhelm Institut für Physiologie, Heidelberg.

artefacts, postmortem changes, whose relation to vital processes is unknown? (2) When three different and apparently unconnected processes are already known to accompany muscle activity, have we not to assume many others, and might it not be that none of the processes known so far are of especial importance in muscular work?

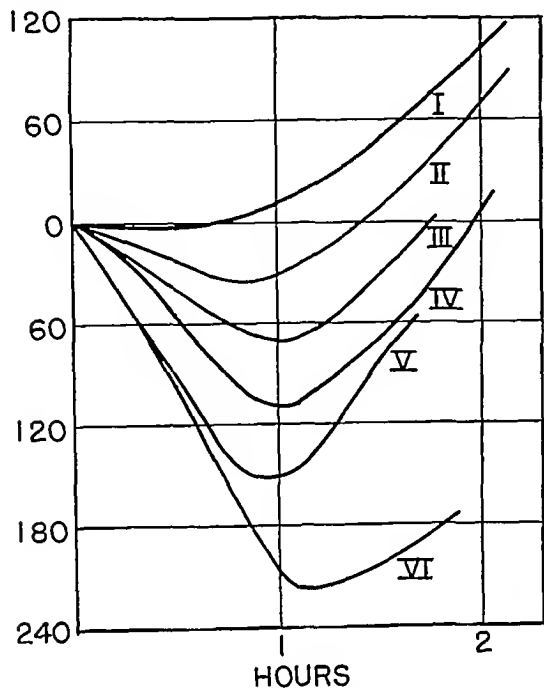

Figure 1 Hydrogen Ion Concentration Changes in Muscle during Fatigue as Measured by Carbon-Dioxide Exchange

Carbon-dioxide output—indicating increased acidity—is measured on the ordinates from zero upward  
carbon-dioxide uptake—indicating increased alkalinity—is measured on the ordinates from zero downward

Curve I	1.1 vol per cent	(pH 7.93)
" II	5.0 " "	( " 7.23)
" III	7.9 " "	( " 6.97)
" IV	16.2 " "	( " 6.75)
" V	34.5 " "	( " 6.45)
" VI	71.5 " "	( " 6.07)

I believe that both objections can be confidently refuted. In respect to the first, it was learned some years ago that the syntheses and decompositions in question were accompanied by changes which could be demonstrated in the living muscle by physicochemical measurements. For example, the alterations connected with the decomposition of creatinephosphate are always contrary to those connected with the breakdown of carbohydrate to lactic acid. Thus Lipmann and I<sup>12</sup> in 1930 found a shift of pH to the alkaline side with the enzymatic splitting of creatinephosphate, and to the acid side with the formation of lactic acid. On

account of the difference between the second dissociation constant of phosphoric acid and that of creatinephosphoric acid, the alkalization connected with this breakdown became the greater the more the initial pH was brought to the acid side by the addition of carbon dioxide. Chemical analysis showed that, on anaerobic stimulation of a normal muscle, at first much creatinephosphate was broken down compared to the amount of lactic acid formed, with increasing fatigue this proportion was shifted so that an increase in the formation of lactic acid resulted. Moreover, the amount of creatinephosphate present was the resultant of the simultaneous breaking down and resynthesis, and hence the amount of the creatinephosphate split was less during recovery than at the height of tetanus. The conclusion is that during a contraction the rate of breakdown corresponds to the development of tension, but that

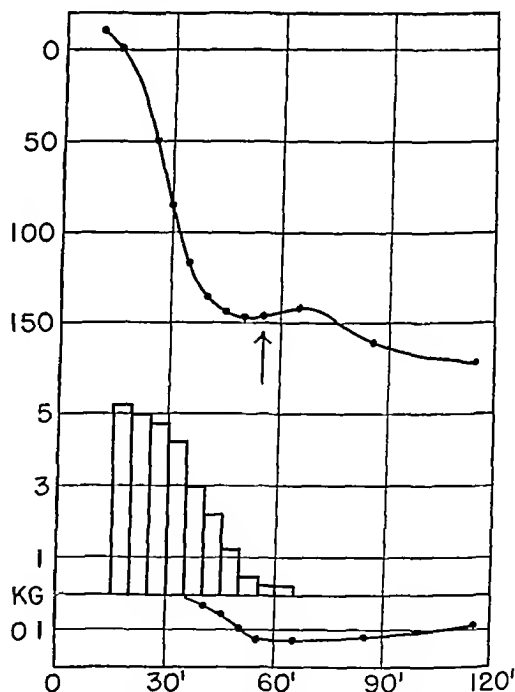

Figure 2 Changes Accompanying Fatigue in a Muscle Poisoned with Iodoacetic Acid

The upper curve represents the carbon-dioxide uptake (cu mm per gram of muscle) in an atmosphere containing 33 vol per cent carbon dioxide. The rectangles represent the sum of tension of twitches per gram of muscle during 5 minute intervals. The lower curve represents the tension of rigor per gram of muscle.

the resynthesis is incomplete with the first contractions, while in the latter ones the resynthesis is more and more complete, so that in the steady state no further breakdown can be observed.

The change in pH of the living muscle during

fatigue corresponds exactly to that predicted by chemical analysis. In a series of contractions, the muscle becomes at first more alkaline and later more acid, and the alkalinity is the more pronounced the higher the concentration of carbon dioxide (Fig 1). In muscle poisoned by iodoacetic acid (Fig 2) the alkalinity increases with fatigue. Chemical analysis proves that the hydrolysis, which is the equilibrium between breakdown and resynthesis, is as large as in normal muscle. However, at the height of tetanus and subsequently there is no resynthesis of creatinephos-

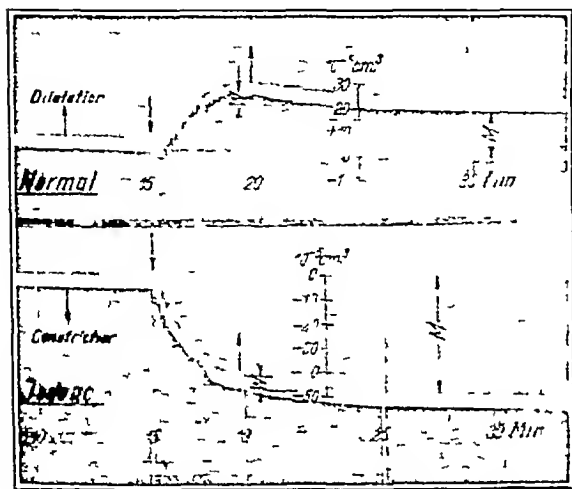

Figure 3 Volume Change in a Series of Tetanic Contractions of 2 Seconds' Duration

The upper curve represents normal muscle undergoing fatigue and the lower iodoacetic-acid poisoned muscle. The distances between the two arrows on each curve designated W give the corrections for the heat of contraction. The distances between the two arrows designated M give the total volume changes per gram of muscle after complete fatigue.

phate or formation of lactic acid. Recently Dubousson<sup>2</sup> measured this pH shift with a glass electrode and thus obtained still more exact results. When the pH is calculated from chemical data in the poisoned muscle, the agreement between

taneously in muscle. As I found with Möhle<sup>22</sup> the molecular volume rises when glycogen is split to lactic acid, it decreases with the splitting of creatinephosphate and also of adenosinetriphosphate. Besides the rapid volume change, discovered by the Hungarian investigators Ernst and Üj,<sup>4</sup> a more protracted one can be observed, which is co-ordinated with chemical reactions. I disregard here the course of the details of the change in volume during single tetanic contractions, and give only two curves which show the total effect. Normal muscle undergoing fatigue (Fig 3) shows at the onset a diminution in volume which accompanies the initial breakdown of creatinephosphate. This decrease is followed by an increase in volume which parallels the excess formation of lactic acid. In muscle poisoned by iodoacetic acid, the diminution in volume is present from the onset, and the shrinking continues until the development of rigor (Meyerhof and Möhle<sup>22</sup>). In regard to volume changes also, the muscle treated with iodoacetic acid shows agreement between calculated and determined values to be almost exact, yet in the normal muscle the effect of lactic acid is smaller than the calculated value, but qualitatively in substantial agreement with the theory.

A study of the changes in transparency of muscle has been made at our institute by Muralt.<sup>24</sup> It will suffice to state that he found that these changes in the muscle corresponded to those predicted from the observed chemical reactions.

We may conclude without reservation that the splittings and resyntheses revealed by chemical analysis really take place during muscular activity.

Experiments on living muscle have demonstrated that a breakdown of creatinephosphate precedes the formation of lactic acid. Therefore the energy of the latter is available for the endothermic resynthesis of creatinephosphate. Thermodynamic calculations on normal muscle and that treated with iodoacetic acid correspond with this conception. The more exact elucidation of this relation was due to experiments on the ex-

A

+ 24000 cal.

B

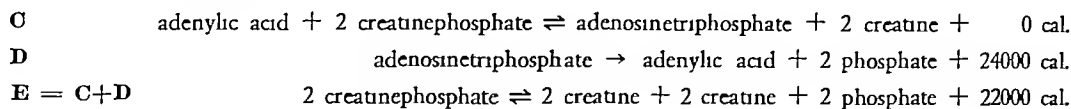

prediction and measurement is almost exact. In the normal muscle the formation of lactic acid is smaller than that calculated from the change in pH, but is still in essential agreement with that predicted.

Other physicochemical measurements also indicate that antagonistic effects are produced simul-

tracts of muscle containing the enzymes. Although such an experiment bears no relation to the events taking place in muscular activity, the chemical reactions can be studied with excellent results. The transformations in energy of these reactions, which are catalyzed by enzymes, calculated per mol, are shown in Reactions A and B.

The values given are those for total energy, which do not coincide with the free energies but do correspond to the myothermic measurements. The heat of splitting of hexosediphosphate into lactic acid and phosphate amounts to 16,000 calories per mol of lactic acid, but in muscle this heat is increased by the neutralization of lactic acid to about 24,000 calories. On the other hand, the

splitting of one mol of creatinephosphate yields 11,000 calories. Very careful experiments by Lundsgaard<sup>18</sup> have shown that during the anaerobic restitution two mols of creatinephosphate are resynthesized for each mol of lactic acid formed after contraction. Thus +24,000 calories for one mol of lactic acid formed is opposed to -22,000 calories for two mols of creatinephosphate resynthesized, so that a slight evolution of heat results.

The well-known measurements of Hartree<sup>8</sup> and Hill<sup>9</sup> have proved that a very small amount of delayed heat is liberated during anaerobic restitution, averaging 5 per cent of the initial heat. The amount is less when the muscle is in good condition. Moreover, under special conditions a transitory endothermic phase has been observed at the beginning of the anaerobic restitution. This phenomenon will be referred to later. Lohmann

Later Lohmann<sup>14</sup> demonstrated that the reverse reaction, namely the splitting of creatinephosphate, caused the synthesis of adenosinetriphosphate. It was therefore obvious that a reversible reaction takes place, as illustrated in Figure 4. The existence of this reaction was proved by Lehmann<sup>11</sup> at our institute. The pH has a great influence on this equilibrium, the amount of

creatinephosphate increases with the alkali.

This reaction is summarized in Reactions C, D and E. Thus 24,000 calories from splitting adenosinetriphosphate is to be compared with 22,000 calories from the splitting of two mols of creatinephosphate, so that the actual heat of the reversible Reaction C is almost zero. If, now, creatinephosphate is to be split into creatine and phosphate, Reaction C has to go to the right, the adenosinetriphosphate has then to be converted into adenylic acid and two mols of phosphate by the action of phosphatases ( $E = C + D$ ). The removal of adenosinetriphosphate (Reaction D) causes Reaction C to go from left to right, and results in a splitting of creatinephosphate. The removal of adenylic acid causes the reaction to go from right to left, and synthesizes creatinephosphate.

This intermediary action of adenylic acid is brought about by the formation of lactic acid in two different ways, with a resultant shift in the equilibrium toward the synthesis of creatinephosphate. To explain this more fully I must briefly describe the sequence of intermediary products of the breakdown of carbohydrate, which in the formation of lactic acid and in alcoholic fermentation are almost identical. The steps involved are indicated diagrammatically in the accompanying scheme. The detailed proof of their validity (Meyerhof, Kiessling, and Schulz<sup>20</sup>) is omitted.

Pyruvic acid may be the starting-point for the formation of either alcohol or lactic acid. In the latter case we have the reduction of pyruvic acid into lactic acid. In the stationary state this reduction reaction is equivalent to the oxidation of triosephosphoric acid into phosphoglyceric acid. The reversible reactions designated by double arrows progress without coenzymes, whereas phosphorylation and hydrogen transfer require coenzymes. The coenzyme for phosphorylation is the adenylic system, that for hydrogen transfer is the coenzyme discovered by Harden, studied by Euler and chemically determined by Warburg.\*

References to this subject may be found in the article by D. Needham in the *Annual Review of Biochemistry*, 1937.

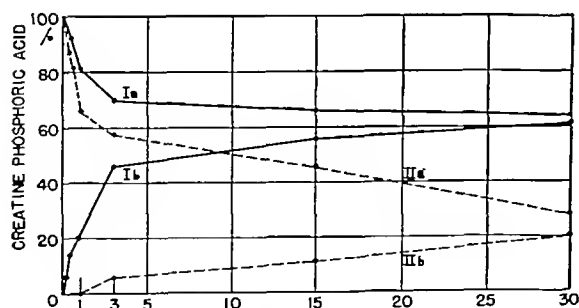

Figure 4

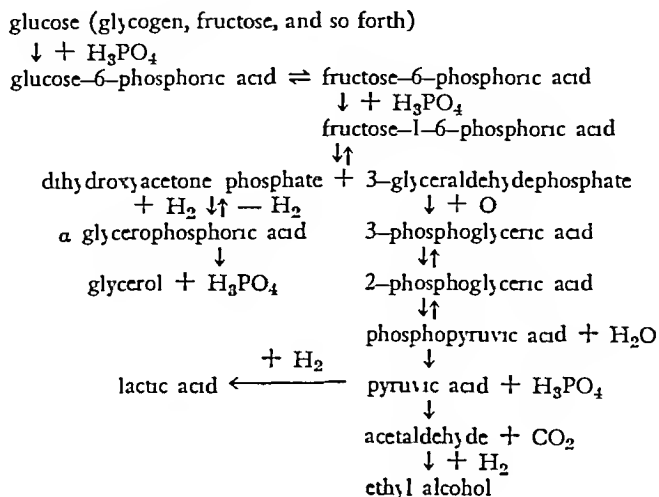

Curve Ia starts from the left side of the equation  
Curve Ib from the right. Curves IIa and IIb show  
the same reaction with excess of creatine

and I found ten years ago that, in an extract of muscle also, creatinephosphate is resynthesized from its split products during the formation of lactic acid. Some years later we<sup>21</sup> observed that the addition of adenosinetriphosphate to a muscle extract caused synthesis of creatinephosphate.

In 1934 Parnas and his associates<sup>25</sup> discovered that phosphopyruvic acid, in both muscle tissue and extracts, on splitting does not set free in-

ceeded in solving this puzzle. Because the splitting of phosphopyruvic acid is the only source of phosphate in these reactions, the synthesis of the

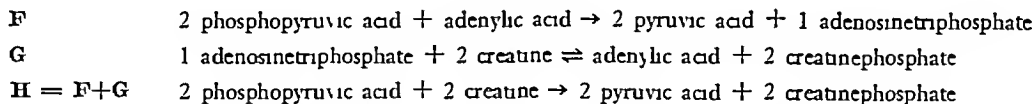

#### BREAKDOWN OF CARBOHYDRATE

organic phosphate, but transfers it to creatine to form creatinephosphate. This is represented in Reactions *F*, *G* and *H*. The adenylic system,

second mol of creatinephosphate cannot be derived from this source. It will now be shown how the second mol of creatinephosphate is

#### PARNAS REACTION

which acts as a catalyzer, does not figure in the end result ( $\text{H} = \text{F} + \text{G}$ ). The splitting of phosphopyruvic acid is an intermediary reaction of the formation of lactic acid also, for one mol of lactic acid and one mol of phosphocreatine are produced for each mol of phosphopyruvic acid hydrolyzed.

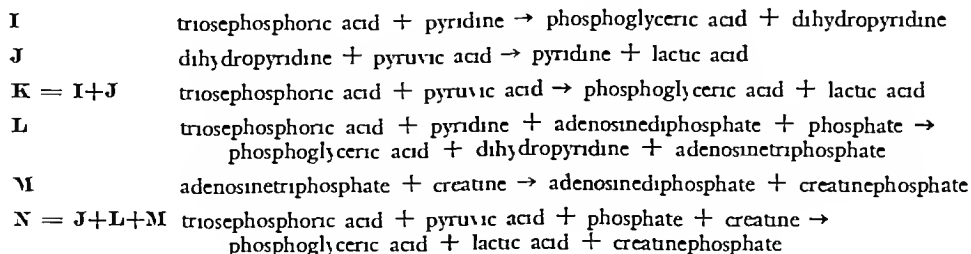

The analysis is, however, not yet complete, for as previously stated, two mols of creatinephosphate are synthesized by muscle for each mol of

brought about by hydrogen transfer.

Exactly as the adenylic system acts as a catalyzer of phosphate transfer, so cozymase interacts as a catalyzer of hydrogen transfer. According to Warburg and Christian,<sup>27</sup> cozymase is a pyridine-nucleotide which takes up hydrogen according to the equation

Experiments at our institute (Meyerhof<sup>19</sup>) show

lactic acid (see Reactions *A* and *B*). But the Parnas reaction yields only one mol. How does the synthesis of the second mol of creatinephosphate come about? Only recently have we suc-

ceeded in solving this puzzle. Because the splitting of phosphopyruvic acid is the only source of phosphate in these reactions, the synthesis of the

action *K* However, if inorganic phosphate and adenylic acid or adenosinediphosphate are present, the reaction goes rapidly Under these conditions the approximate Equation *L* is valid This is followed by the rapid reaction represented by Equation *J* The adenosinetriphosphate formed according to Equation *L* is reconverted into adenosinediphosphate according to Reaction *M* At the same time the creatine is phosphorylated, thus providing for the formation of the second mol of creatinephosphate The end result of the reaction is given in Equation *N*

The adenylic and the pyridine systems serve only as catalyzers and do not appear altered in the final reaction Rapid oxidation and reduction take place between triosephosphoric acid and

Table 1 Total Balance

C Creatinephosphate	+60	D/A	1.55	2
D Lactic acid	+24			

pyruvic acid For each mol of lactic acid formed one mol of creatinephosphate is synthesized from creatine and inorganic phosphate The energy from the oxidation-reduction reaction is utilized for the synthesis of creatinephosphate

The energy balance for all these reactions has not only been calculated but has also been measured calorimetrically The heat evolved from the splitting of sugar to lactic acid, without counting the heat of neutralization, is + 16,000 calories per mol The heat of splitting phosphopyruvic acid into pyruvic and phosphoric acid is + 8000 calories In the Parnas reaction this + 8000 calories is to be balanced against - 11,000 calories from the synthesis of one mol of creatinephosphate, so that the complete reaction has a negative heat of 3000 calories Therefore of the total heat incident to the formation of lactic acid, + 16,000 calories, half is accounted for by the splitting of phosphopyruvic acid There remains only half the total heat for the sum of all the other reactions which result in one mol of lactic acid This heat is the result of different components with opposite signs When we disregard the sources, 8000 calories is available for the synthesis of the second mol of creatinephosphate, although 11,000 are required

The total changes may then be summarized as follows When we convert hexosediphosphate, in a suitable enzyme extract, in the presence of cre-

atine and phosphate, taking into account the Parnas reaction and that described above, we can calculate and measure the total energy transfers, as shown in Table 1 Four mols of creatinephosphate are synthesized from one mol of hexosediphosphate and two mols of inorganic phosphate In Table 1 are given the actual figures of an experiment in which the energy transfer is calculated in terms of 10<sup>-4</sup> mol per cubic centimeter of muscle extract For example, 60 x 10<sup>-4</sup> mol of creatinephosphate is synthesized from 15.5 x 10<sup>-4</sup> mol of hexosediphosphate The ratio found is 3.9 instead of the calculated ratio 4.0 (Meyerhof, Schulz, and Schuster<sup>23</sup>) The formation of two mols of lactic acid is strongly endothermic (-12,000 calories)

As an example of the rates involved in this reaction, two calorimetric measurements are given in Figure 5 In the one case neutralization was

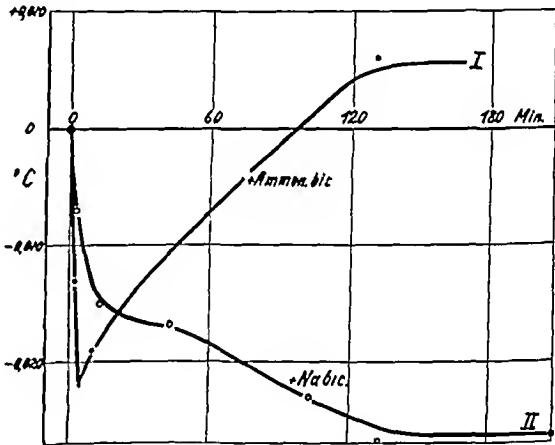

Figure 5 Course of the Heat of Reaction (Meyerhof<sup>19</sup>)  
Curve I in presence of ammonium bicarbonate shows great heat of neutralization, Curve II in presence of sodium bicarbonate shows small heat of neutralization

effected by sodium bicarbonate and in the other by ammonium bicarbonate With the former the total reaction is endothermic because the heat of neutralization is small The temperature falls rapidly at first, and then more slowly Neutralization with the latter gives values similar to that of protein The initial negative heat phase is followed by a positive heat neutralization and the total is slightly positive This curve resembles that for the heat of the anaerobic restitution of muscle as found by Hartree<sup>8</sup> when working under especially suitable conditions I think that these calorimetric measurements in enzyme extracts render a most perfect analogy to the rate of heat production in the anaerobic restitution of living muscle

These peculiar reactions are of great significance in the metabolism of living muscle The presence

of free creatine and free phosphate during the formation of lactic acid by the muscle enzymes is important not only for the thermodynamics of the reaction but also for its velocity. As is well known, hexosediphosphate is decomposed slowly, a phenomenon which has prevented many investigators from considering this compound as a precursor of lactic acid or alcohol. In fact the triosephosphate originating from hexosediphosphate reacts very slowly in an enzymatic system with cozymase. However, this reaction becomes rapid as soon as inorganic phosphate, as an acceptor, and a little adenylic compound, as catalyzer, are present. In alcoholic fermentation the phosphate acceptor is glucose, but in muscle it is the very creatine which immensely accelerates the reaction. This sequence is graphically presented in Figure 6.

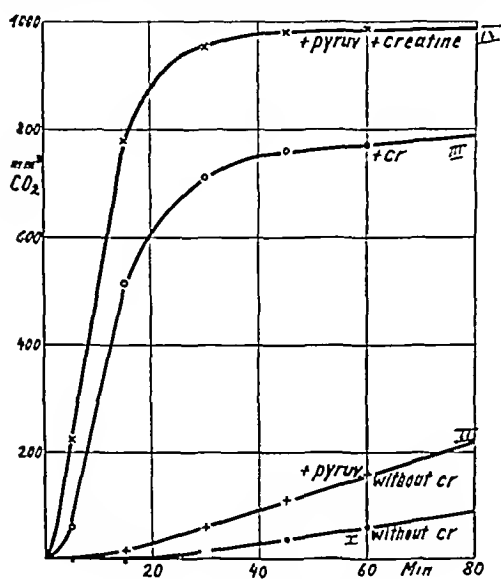

Figure 6 Creatine Effects

Effect of creatine on the velocity of the breakdown of hexosediphosphate (Curves I and III) and of the reaction between pyruvic acid and triosephosphate (Curves II and IV)

for an enzyme extract with and without creatine, for the total breakdown of hexosediphosphate, and also for the reaction between pyruvic acid and triosephosphate. The increase in the velocity of the breakdown of hexosediphosphate by the coupling with the synthesis of creatinephosphate is of extreme significance in the kinetics of this reaction in muscle. In fresh muscle, only hexosemonophosphate is present in large quantities. It can be shown by special experiments that hexosemonophosphate reacts only after it has taken up one mol of phosphate and become hexosediphosphate, which is the general intermediary in the formation of lactic acid. So long as the muscle is resting, creatine is present as creatinephosphate

and the lactic acid formation is minimal. But when muscle contracts, creatinephosphate is split into creatine and phosphate, and lactic acid is rapidly formed and released, as can be seen during the restitution period of muscle. This lactic acid induces the resynthesis of creatinephosphate as described above, and with the return to the original state, the formation of lactic acid ceases. By this means the total energy of carbohydrate breakdown is transferred to the resynthesis of creatinephosphate.

In muscle poisoned by iodoacetic acid the reactions can be similarly interpreted in so far as this coupling is concerned. Iodoacetic acid inhibits oxidation and reduction, and hence the triosephosphoric acid does not undergo any further reaction. Since there is no lactic acid, creatinephosphate which has been split cannot be resynthesized, because both kinds of phosphate transfer are lacking, namely the formation of phosphoglyceric acid and the splitting of phosphopyruvic acid. Anaerobically the free creatine remains unchanged. The free phosphate esterifies more glycogen, with the formation of hexosemonophosphate and hexosediphosphate. Apparently, as the experiments of Cori and his co-workers<sup>1</sup> and Parnas and Baranowski<sup>28</sup> have shown, this esterification of glycogen, as opposed to that of hexose, proceeds even without an oxidation-reduction reaction. Thus, when creatine is not available as a phosphate acceptor, the hexosemonophosphate and hexosediphosphate become the main products. The adenosinetriphosphate is preserved in the poisoned muscle so long as creatinephosphate remains. It breaks down only afterward, because the synthesis of adenosinetriphosphate is effected by the reaction of Lohmann<sup>14</sup> (see Reaction D), and ceases when this breakdown comes to an end.

The processes of the anaerobic restitution of muscle discussed here form only a small part of the chemical description of muscle activity. Many questions are as yet unanswered. Even the reactions here described require further elucidation. Especially requiring further study is the problem of why the simultaneous uptake of inorganic phosphate by the adenylic system accelerates the reduction of cozymase. In any event, it must be acknowledged that our understanding of the chemistry of muscle is considerably advanced over that of ten years ago. The older conception of the energy relations between the formation of lactic acid and the resynthesis of phosphagen can now be replaced by definite interdependent chemical reactions. By the elucidation of these reactions science has succeeded in at least partially unveiling one of life's fundamental processes.

## THE VITAMIN C STATUS OF DIABETIC PATIENTS\*

VILMA SEBESTA, MD,† RACHEL M SMITH, B.A.,‡ ALISON T FERNALD, BS.,‡ AND  
ALEXANDER MARBLE, MD§

## BOSTON

THE physiological significance of vitamin C has become increasingly recognized since its identification as ascorbic acid<sup>1 2 3 4</sup> and the adaptation of simple methods for its determination. Recently several investigators have reported an effect of vitamin C on diabetes and carbohydrate metabolism. Roller<sup>5</sup> in 1936 reported that the administration of vitamin C caused a diminution of the glycosuria in diabetic patients. He also observed a lessened rise in blood sugar during food-tolerance tests if 1000 to 3000 mg of ascorbic acid was given with the food. In the same year Stoicesco and Gingold<sup>6</sup> reported in normal individuals a fall in blood sugar following the intravenous injection of 240 mg or the oral administration of 500 mg of vitamin C. In diabetic patients the results obtained were variable. Similarly Stepp, Schroeder and Altenburger<sup>7</sup> reported a lowering of blood sugar in normal individuals following a single intravenous injection of ascorbic acid but no effect from oral administration. These authors also observed in normal individuals, but not in those with diabetes, an increased hypoglycemic action of insulin following the simultaneous injection of vitamin C and insulin. Pfeiffer and Scholl,<sup>8</sup> under different conditions of vitamin

C saturation, confirmed in part the latter observation and in addition reported marked deficiency of vitamin C in the cases of diabetes studied. Schroeder<sup>9</sup> supported the idea of a deficiency of vitamin C in diabetic patients with evidence that retention after the intravenous injection of 150 mg or the daily oral administration of 300 mg of ascorbic acid may be as great as 97 per cent. Aszodi and Mosonyi<sup>10</sup> claim that vitamin C, especially if combined with vitamin B<sub>1</sub>, may be used in mild cases of diabetes to supplant insulin. Their study is particularly interesting as it is based on the assumption that, since vagotonic effects are known to follow injections of vitamin C, there might well be a stimulation of the pancreas through the vagus, causing an increased insulin secretion. As evidence they show the lowering of the blood sugar of mice following an injection of either human or dog serum taken from a subject previously injected with vitamin C.

In contrast to the above evidence suggesting a more or less specific bearing of vitamin C on glucose tolerance, sensitivity to insulin and carbohydrate metabolism in general, are the completely negative findings of Kreitmair<sup>11</sup> and Armentano and his co-workers<sup>12</sup>. These authors deny any specific relation of vitamin C to diabetes.

The present paper deals with the vitamin C status of a representative group of diabetic patients under observation in the George F Baker Clinic. The study is based on determinations of

of diabetic patients to the intravenous injection of a single large dose of ascorbic acid (1000 mg)

#### SELECTION OF PATIENTS

Seventy-seven adult patients with proved diabetes were selected as subjects. There were 31 men and 46 women. The ages varied from fifteen to seventy-six, most patients being over fifty. In so far as possible, patients with diabetes under good control were chosen. The length of stay in the hospital prior to the test varied from one to one hundred and twenty days, in most cases three to eight days. Some patients were included who, although suffering from lesions of the extremities, or convalescing from operations for them,

tioning, and in most cases it seemed reasonably adequate. This might be expected because in 36 of the 49 cases listed in Table 1 the duration of diabetes was of more than one year and in 33 of more than two years, and during this time almost all the patients had been following, more or less faithfully, diets which included vegetables and fruit in adequate amounts. The hospital diet averaged carbohydrate 142 gm., protein 68 gm and fat 85 gm per day, and as the chief source of vitamin C it included two or three daily servings of raw fruit and vegetables. Some vitamin C may also be assumed to have been derived from the cooked part of the diet.<sup>14</sup> Calculated roughly, the daily average minimum intake of vitamin C on the

hospital diet may be taken as 80 to 140 mg, at least twice as much as the 40 to 60 mg considered as the daily human requirement<sup>15 16 17</sup>

#### METHODS

The method used for the determination of vitamin C was the 2, 6-dichlorophenolindophenol titration procedure of Tillmans<sup>2</sup> For urine the Harris-Ray modification<sup>18</sup> was employed, and for blood the macro procedure as outlined by Farmer and Abt<sup>19</sup> The indicator (La Motte) was dissolved in freshly boiled distilled water (85°C), and was prepared so that 1 cc was equivalent to about 0.05 mg of ascorbic acid The dye solution was standardized against known ascorbic acid (Merck's Cebione) and preserved in a glass-stoppered brown bottle in a refrigerator Under these conditions it maintained its strength for two or three weeks

Our procedure was as follows A fasting blood sample was taken, and immediately afterward 1000 mg of Vitamin C Injectable\* was given intravenously The urine voided during the following five hours, including that voided at the end of the period, was collected and kept in the refrigerator until just before titration As preservative, sufficient glacial acetic acid was used to give the total sample a pH of between 3 and 4 Under these conditions we found no appreciable loss of ascorbic acid during the five-hour interval At the end of the collection period the urine was measured and a convenient dilution (usually 1:100) was made for titration Titration was carried out immediately and completed within one minute There was seldom any difficulty in obtaining a sharp endpoint in the diluted urine sample

The blood plasma was precipitated as soon as possible, and the titration carried out, usually within one hour of collection

For normal values in the saturation test we have used the figures suggested by Wright,<sup>13</sup> who states that normally 400 mg or more of the total 1-gm dose is excreted during the first five hours For fasting blood values we have taken 0.80 mg per cent as the lower limit of normal

#### RESULTS

Table 1 shows the results obtained in 49 of the 77 diabetic cases and Table 2 those obtained in the 6 normal ones Two points are evident First, the vitamin C values obtained in the patients with uncomplicated diabetes were in general within a normal range and compared very favorably with those in the normal individuals, although on the average the latter were at a higher level Second-

ly, the surgical cases tended to have either a lowered blood ascorbic acid or a diminished urinary excretion or both

Of the total of 49 diabetic cases only 6 showed definitely low values in both blood and urine, not only with the blood ascorbic acid under 0.80 mg per cent, but also with the urinary excretion during the five-hour period under 400 mg Of these cases, 4 (Cases 1, 2, 9 and 13) were surgical Therefore in only 2 of 49 cases of uncomplicated diabetes was there any striking indication of vitamin C deficiency

That the fasting blood value usually bears a direct relation to the excretion is also evident from Table 1 In the cases in which a discrepancy may be noted, usually either the blood or urine value is a borderline figure or the patient falls in the surgical group Thus, of 7 cases with blood values under 0.80 mg but with urine excretion over 400 mg, 3 gave borderline figures with excretions under 410 mg Two of these, and 1 other of the 7, were surgical patients Similarly of the 8 cases with blood values above 0.80 mg but with excretion under 400 mg, 5 were surgical cases and 4 had borderline blood values between 0.80 and 1.03 mg

If we omit, therefore, all cases showing low values in which any surgical lesion might be a complicating factor, 9 diabetic patients out of a total of 49 cases gave some indication of a lowered vitamin C status 2 (Cases 3 and 5) showed definite vitamin C deficiency, with blood ascorbic acid less than 0.80 mg per cent and urine excretion for the five-hour period well under 400 mg; 3 (Cases 16, 35 and 48) showed lessened excretion but normal blood values, and 4 (Cases 4, 5, 7 and 12) showed blood values under 0.80 mg per cent but excretion above 400 mg Of the remaining 40 cases, either both blood and urine values were above normal or a surgical complication could account for one or both lowered values Only 1 patient (Case 46), with a lesion of the extremities serious enough to demand operation, had high values in both blood and urine

The results obtained in the first 28 diabetic patients studied were discarded, and the data were not included because certain technical discrepancies were discovered which we felt invalidated the strict accuracy of the figures obtained It is of interest to note, however, that in this group the general findings agree with those already stated In most cases consistent values were obtained in the fasting blood sample and the five-hour excretion, and of those cases showing a low value for the five-hour period 58 per cent were surgical cases

## DISCUSSION

The data presented above indicate clearly that in our series the average patient with uncomplicated diabetes can and does have a normal status as regards vitamin C. It must be remembered that our results were obtained with patients in a private hospital, and that findings in a large public clinic might be quite different. Our results are of significance, however, in ruling out any marked influence of the diabetes per se. The normal status of the patients observed in the present study no doubt reflects the adequate amounts of vitamin C afforded by the fruit and vegetables in their usual diet. With the increasing and laudable tendency to make diabetic diets more nearly like normal ones, this conclusion emphasizes anew the value of fruit, especially citrous fruit, and green vegetables, as included in the classic dietaries for patients with diabetes.

In our study, as previously stated, we have accepted Wright's values as a normal response to his

saturation test. Ralli's recent work<sup>20</sup> with a series of 12 normal individuals, although she used smaller doses, tends to confirm the validity of Wright's results. Although the term "saturation" is somewhat vague and saturation tests are perhaps justly criticized as creating distinctly unphysiologic conditions, recent investigators seem to favor this method of determining the vitamin C status of an individual. The saturation test based on a single large dose of vitamin seemed more suited to our facilities than one involving a more prolonged period. The size of the dose obviated any slight effect of dietary variations during the test, and the analysis of urine high in vitamin content and preserved only five hours eliminated many technical difficulties inherent in the indophenol titration of urine.

Although the reliability of results obtained by the direct titration of urine with indophenol may be questioned owing to the presence of interfering substances, there is good evidence that

after a large dose of vitamin C the reducing substance in the urine is chiefly ascorbic acid.<sup>21, 22</sup> The suggestion of van Eekelen and Heinemann<sup>22, 23</sup> that the urine of diabetic patients differs from normal urine in its larger content of non-specific reducing material, particularly thiosulfate, has not been apparent in our work. In view of the experiments of Heinemann,<sup>24</sup> no particular difference would be expected provided that there was no evidence of abnormal protein catabolism in the diabetic patient and that his protein intake corresponded closely to that of the normal controls.

As regards any difference between the normal and the diabetic individual in retention of ascorbic acid, our results, as evidenced in Tables 1 and 2, are in entire disagreement with those of Schroeder,<sup>9</sup> to whose work reference has been made. He asserts that after a given dose the diabetic patient retains a much greater proportion of ascorbic acid than does the normal individual and that with an intravenous injection of 150 mg the retention may reach 97 per cent, even if the injection is repeated for several days, similarly 91 to 97 per cent was retained after the oral administration of 300 mg. These figures imply an excretion of only 3 to 9 per cent. From a study of the literature on urinary excretion and retention with which we are familiar, no explanation of such a low excretion seems probable except a diet definitely poor in vitamin C. It would be of interest to know the vitamin C content of the "usual diabetic diet" referred to by Schroeder, and also the blood ascorbic-acid levels of his patients.

It may be observed from Table 1 that several of our patients showed high fasting blood-sugar values. Ralli's<sup>25</sup> statement that the reabsorption of vitamin C and that of glucose do not involve a common mechanism justifies us in assuming that vitamin C absorption and excretion are independent of glucose absorption and excretion, and that high blood-sugar values probably do not influence vitamin C results.

Surprising to us were the low values obtained for both blood and urine ascorbic acid in surgical cases. These results were unexpected because, realizing the influence of infections on the vitamin C requirement, we carefully chose surgical patients long removed from active infection and from any surgical procedures. Our tests on this group were usually performed just prior to the patient's discharge, at a time when local lesions were uninfected and insignificant. The surgical patients were without exception those whose lesions were of the extremities. Because of the nature of the operations and of the anesthesia (usually low spinal), surgical procedures caused little or no interruption to the usual diet. It

seems likely that the generally lower economic status of the patients in the surgical group was partly responsible for the lower vitamin C values obtained

In order to detect any possible hypoglycemic action of vitamin C, in a considerable number of cases the blood sugar was followed during the saturation test. Table 2 shows the results obtained with normal individuals in the fasting state. These persons obviously were in excellent vitamin C nutrition. It is clear that the injection of either 300 or 1000 mg of ascorbic acid had no effect whatever on the blood sugar.

In the diabetic cases similarly studied the blood sugar was followed first on a control day, and then on the day on which the injection of 1000 mg of vitamin C was made. Determinations were made before injection and at two-hour intervals afterward for a period of six hours. These patients and the 4 normal individuals likewise treated were not fasted, and the unavoidable variations in blood sugar, particularly in the diabetic cases, due to intake of food make the results difficult to interpret. The data, though not presented here, confirm, however, the completely negative findings secured with the fasted normal individuals. Our results suggest, therefore, that vitamin C has no significant effect on the blood sugar of individuals in good vitamin C nutrition. Whether the point of good vitamin C nutrition is a fundamental one we are not in a position to state, but the work of Sigal and King<sup>26</sup> suggests that possibility. They found a significant rise in fasting blood sugar and a distinctly lowered glucose tolerance in guinea pigs kept for ten to twenty days on a diet depleted in vitamin C but normal in other respects. A striking return to normal was found within fifteen days after vitamin C was restored. If a deficient diet incident to poor economic conditions causes in some large groups of diabetic patients a condition bordering on a state of subclinical scurvy, this work may offer an explanation of some of the conflicting reports in the literature.

#### SUMMARY

The vitamin C status of 77 adults with diabetes mellitus was determined. Results are reported in detail for 49 patients.

Patients with uncomplicated diabetes whose vitamin C intake had been adequate showed levels of blood ascorbic acid (fasting) above 0.80 mg per cent, and excreted in five hours upward of 400 mg of ascorbic acid in the urine in response to a 1000-mg test dose given intravenously.

Patients confined to bed with surgical lesions, usually of the extremities, even with no fever or

apparent infection, tended to show low normal or subnormal values. This may in part reflect a deficient vitamin C intake (prior to hospital admission) incident to an economic status lower than that of the majority of the patients studied.

With 4 normal individuals in good vitamin C nutrition no effect on the blood sugar could be observed after the intravenous injection of either 300 or 1000 mg of ascorbic acid.

## CYSTOCELE REPAIR\*

Factors Which Necessitate Changes in the Usual Procedure,  
With Suggested Technics

JAMES R. MILLER, M.D.†

HARTFORD, CONNECTICUT

THIS paper discusses some of the complicating situations which make it necessary to alter the usual methods employed in the repair of cystocele. Such repairs are usually a part of more general prolapse operations, and it is unavoidable that the larger problem of prolapse repair be also discussed here. In the last few years I have been surprised to note how frequently such complications are seen, and have observed that little help for the inexperienced operator is to be found in textbooks.

An almost infinite variety of situations may be present. Correct evaluation of the various factors involved and judicious variation of operative methods are necessary if a result satisfactory not only to the surgeon but to the patient is to be obtained. Only a few of the complicating situations will be discussed, and it is assumed that there has been a general acceptance of the thesis that hernias of the uterogenital hiatus are most advantageously repaired by the vaginal route. The general principles of such repair were admirably summarized two years ago by Ward<sup>1</sup> in an address before the British Congress of Obstetrics and Gynecology.

Suspension of the uterus or abdominal fixation has little place in this field, and such operations frequently interfere with an adequate vaginal repair if this is necessary at a later date. Several years ago I discussed before this society the case of such a patient, whose prolapse had been subjected on three previous occasions to abdominal suspension. At the last operation an actual fixation of the fundus to the abdominal wall was done, this fixation held the uterus but a large cystocele recurred. I was able to obtain a lasting satisfactory repair by cutting loose the fundus from its abdominal attachment, closing the abdomen and immediately performing a vaginal hysterectomy with the usual repair. Several other cases have been seen in which a well-sustained round-ligament suspension operation made subsequent repair of a cystocele quite difficult.

It is a *sine qua non* in plastic surgery that ideal conditions must obtain, especially as regards infection, before a successful operation can be contemplated. It is my belief that no cystocele or

other major vaginal repair work should be done in the presence of a complete tear of the anal sphincter. Certainly this is true if such a tear allows incontinence of feces sufficient to alter the bacterial flora of the vagina. In such cases it is wiser to repair the anal sphincter first and complete other vaginal procedures at a later date. Fortunately this complication is seldom seen, for complete perineal tears are most likely to occur in the patient who has a funnel pelvis, the narrow pubic arch not only forming a secure attachment for the connective-tissue support anterior to the cervix but protecting this area from injury by the baby's head during delivery. I have, however, operated on 2 such patients by the two-stage procedure.

Where the cystocele presents the principal lesion from the points of view of both symptoms and deformity, I have found the interposition, or more properly the transposition, of the uterus a highly valuable and satisfactory method. The cervix is amputated whenever it is diseased, but this complicates the operative procedure, and in recent years I have been inclined to give up the interposition operation where the cervix had to be amputated and to perform the so-called Manchester type of operation instead. The interposition operation is further limited in its scope by the following considerations: the uterus must be approximately normal in size, cancer must be ruled out and further childbearing must be eliminated. If an enterocele is present its repair complicates the interposition operation and makes me favor the Manchester procedure or vaginal hysterectomy. I have also found the interposition operation a poor method where there is more than first-degree descent of the uterus. On the other hand, many patients having a cystocele with partial incontinence have been greatly benefited by the interposition operation, owing, no doubt, to the pressure of the transposed fundus against the symphysis. Whenever the intra-abdominal pressure is increased, this pressure of the uterine fundus is sufficient to compress the urethra and control the voluntary type of incontinence.

Poor results of prolapse repairs are frequently due to a failure to recognize and obliterate properly an enterocele or cul-de-sac hernia. I recently saw a patient of seventy-five with a pro-

\*Read at the annual meeting of the New England Surgical Society, Boston, September 30, 1938.

†Visiting obstetrician and gynecologist, Hartford Hospital.

trusion of the cervix outside of the vulva. She had just been operated on suprapubically for relief of a large bladder stone. Ten years before this, one of my gynecological colleagues had repaired the cystocele but had failed to amputate quite enough of the cervix or to repair a deep enterocele. The cystocele repair was perfectly sustained, although the cervix was pulled too close to the symphysis. This undoubtedly accentuated the cul-de-sac hernia and placed the cervix far in front of the mid-axis of the pelvis in a position where prolapse was inevitable. I believe that the bladder stone, the result of chronic cystitis, was due to a sacculation of the bladder not in its usual cystocele area but on top of and behind the atrophied uterus. Pessaries are of no use in a case of this sort, and proper repair at the present time involves considerable risk. This case is discussed not only from the point of view of failure to repair the enterocele but to emphasize the necessity of locating the cervix in, or if possible behind, the mid-axis of the pelvis where some support may be obtained from the perineum.

That perineal support is not always effectual, however, is shown by the following experience. Six years ago I operated on a patient fifty years old to repair a large enterocele and rectocele, building up so high and firm a perineum that there was subsequently considerable complaint from dyspareunia. Two years ago the patient had an emergency laparotomy for gangrene of the omentum, and during convalescence considerable straining occurred due to vomiting. Almost immediately after convalescence she noted increasing symptoms from a cystocele which was not present at the time of my first operation. Repair of the cystocele and urethrocele was done although an extensive perineotomy was necessary. While no well-developed cystocele was present when I first saw this patient, I feel reasonably certain that there must have been some recognizable weakness of the pubocervical tissue. I do not advise routine repair of the anterior vaginal wall, but I do believe that even slight weaknesses of this tissue should be repaired, especially in women who may subsequently be called on to do heavy work. This is especially true where the operation is done before the menopause has set in, and where due regard must be given to the possibility of future hernia caused by the atrophic process of the menopause.

One year ago I was faced with a very unusual complication in a patient of only fair physical condition, aged seventy. She had a second-degree prolapse of the uterus with cystocele and rectocele and a true prolapse of the urethral mucosa. About half the urethral wall had everted, form-

ing a mushroom-like tumor 3.5 cm in diameter, portions of which were gangrenous. The patient was immediately sent to the hospital, and the prolapse of the urethra was reduced and corrected by the ingenious method devised by one of our members, Dr. Thomas N. Hepburn.<sup>2,3</sup> This method consists, as is well known, of an extra-peritoneal suprapubic incision, rapid blunt dissection of the space in front of the bladder and urethra, and suspension of the urethra and bladder neck to the posterior wall of the symphy-

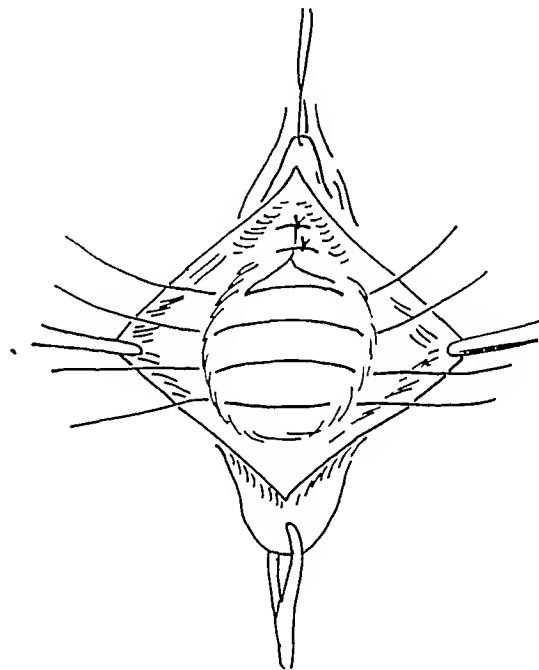

Figure 1 A Commonly Employed Method of Reduplicating the Bladder Fascia

*In the Manchester type of operation the lower sutures also grasp the anterior surface of the uterus. Inadequate attention to the bladder neck and middle urethral sphincter is illustrated.*

sis, the upper sutures fastening the wall of the bladder just above the bladder neck to the undersurface of the rectus fascia near its insertion in the symphysis. This patient voided voluntarily and made an uninterrupted recovery without permanent damage to the urethral mucosa. In order to prevent the cystocele and prolapse from dragging down the suspended urethra a Gellhorn pessary was worn for four months, and the prolapse was then repaired by the Le Fort method. Subsequent examination showed that the urethra had retained its high position, that there was no recurrence of prolapse, and that the patient was perfectly comfortable.

Ordinarily the patient with a cystocele is interested in two things, the relief of protrusion, and

the relief of partial urinary incontinence or difficulty in emptying the bladder. Any of the usual methods will satisfactorily overcome the protrusion, but a complete restoration of normal urinary function is a more difficult affair. We distinguish two types of incontinence: that due to inadequacy of the involuntary bladder-neck sphincter, which occurs usually at night, and that which occurs on coughing and sneezing owing to inadequacy of the voluntary middle sphincter of the urethra. Kennedy<sup>4 5 6</sup> has shown that the middle sphincter is functionally and anatomically a portion of the levator musculature, and that this type of incontinence is due either to a stretching of this sphincter or distortion of the lumen of the urethra.

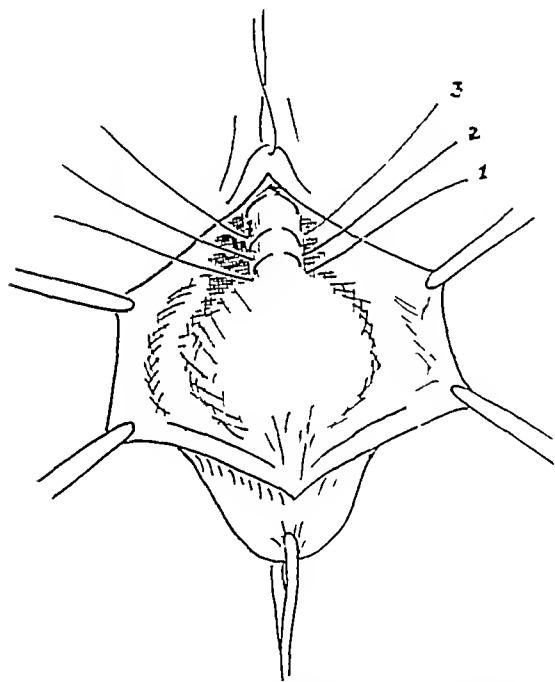

Figure 2. Showing the Extensive Lateral Mobilization Necessary to Allow Adequate Repair of the Urethral Sphincters

*Mattress sutures are placed so that the supporting sling of the middle sphincter is reconstructed; this elevates the urethra and bladder neck.*

by scar-tissue contraction of lacerations of the sphincter. Satisfactory results can be obtained by freeing the entire posterior surface of the urethra and removing any distorting scar tissue, following this by reefing of the middle sphincter with mattress sutures, placed in the same manner as advocated by Kelly for incontinence at the bladder neck.

Kennedy's work has called attention to one of the principal sources of dissatisfaction in cystocele repair operations, and he emphasizes a point which many of us have already observed, namely that

many women with a complete prolapse have no incontinence on straining until the floor of the bladder has been elevated by what seems to be an adequate pelvic repair. We are then surprised to find that incontinence on straining is almost a worse complaint than the previous prolapse. It is obvious that we must recognize the need for proper repair of the middle sphincter when we are repairing the bladder hernia.

Since following Kennedy's procedure I have had fewer failures in this regard. The operation is much more radical, and carries with it the necessity of catheter drainage for one or more weeks postoperatively. Employment of a retention catheter for at least five days is useful. Bladder irrigations are given from the first day until well after voluntary urination and complete emptying have been observed. It is useful to pass a urethral sound if the patient has been unable to void by the tenth day, in order to dilate the urethra, which may have been repaired too snugly. Giving bladder irrigations from the start has minimized the incidence of postoperative cystitis. During the last year I have been forced to perform this operation on several patients who had previously had what seemed to be an adequate cystocele repair.

One of the most interesting complications which we meet is the presence of a cystocele and a fair-sized uterine fibroid tumor in the same patient. When first seen, especially if the fibroid involves the cervix or the lower fundus, the cystocele may not be in evidence, and may not be noted until a later date if a supravaginal hysterectomy be done. If, however, a total hysterectomy is performed, one is able to observe the enormous dilation of the vagina and to note the presence of a cystocele. Following the work of others and inspired by watching Dr. Joe V. Meigs, I have with great satisfaction combined total hysterectomy with repair of the cystocele done by the abdominal route. This is made more difficult by extreme obesity, and necessitates the careful disinfection of the vagina before operation. I have found it to be a straightforward procedure which has given excellent postoperative results and which can be performed as quickly as if done from below. The repair of the perineum and rectocele can be done at the close of the operation if the patient's condition warrants. There is only one technical drawback to this procedure: it is not so easy to repair a urethrocele and an inadequate middle sphincter as it is by the vaginal method of Kennedy. In one case I tried with only partial success to do this by combining total hysterectomy and cystocele repair with a suspension of the urethra as proposed by Dr. Hepburn. The follow-up showed an entirely adequate result so far as the cystocele

was concerned, although there remained some rolling down of the suburethral structures. The urinary function, however, was quite normal, and a subsequent urethral repair of the Kennedy type may be done if necessary.

Serious physical debility caused by old age or by any major organic disease is not necessarily a bar to successful reconstructive pelvic surgery, although a proper choice of anesthesia and operative technics which cause little strain are necessary. In the feeblest patient one can afford marked relief by the Le Fort operation and I have been especially impressed with the modification of this technic suggested by Goodall and Power,<sup>7</sup> of Montreal. This modification lends itself most easily to include an adequate repair of the urethral sphincter and of the rectocele.

#### CONCLUSION

This paper has presented only a few of the many complicating situations met with in reconstructive vaginal repair work. In no branch of surgery do experience and ingenuity count so largely for success as in plastic work. We should study most carefully our failures, for, as Carlisle said, "It is more profitable to reckon our defects than to boast of our successes."

#### DISCUSSION

DR. JAMES B. WOODMAN, Franklin, New Hampshire. One thing in Dr. Miller's very interesting paper which impresses me is his assertion that no one type of operation for cystocele seems applicable to every case. That this must be so becomes evident when we consider that there are first, second and third degrees of prolapse, all accompanied by more or less stretching and dragging down of the bladder and rectum. There are also those cystoceles and rectoceles which have little if any prolapse.

The fact that we have run the gamut of operations, from the old Emmet butterfly procedure to the interposition operation and vaginal hysterectomy, and are still looking for a more satisfactory method, indicates that Utopia has not been reached, and that each case presents a problem in itself.

I have frequently seen cases of prolapse and cystocele in which operation has been followed by recurrence. In treating several of these I used a procedure described some

years ago by the late Dr. H. L. Smith, of Nashua. This operation seems most applicable in the cases of old women where there is a marked postoperative cystocele, with a highly mobile uterus and some degree of secondary prolapse, and in which there is no connecting band between the fundus of the uterus and the abdominal wall. The cervix is grasped and drawn down. An elliptical plate of mucosa from the anterior vaginal wall is taken off down to the bladder musculature. The anterior edge of this section should be about 2 cm. behind the urinary meatus, and the denuded portion toward the cervix should include that structure, the cervical surface being denuded deeply and nearly to the margin of the cervical os. These two points are the most important ones of the procedure, and their observance will prevent later protrusion of the cervix.

The denuded elliptical area is closed with chromic catgut sutures in a transverse line up to the cervix on both sides. Two heavy sutures are passed in an anteroposterior direction through the sides of the cervix close to the denuded section, and up under the symphysis pubis on each side of the urethra. They should be passed close to the bony structure to ensure firmness. If the uterus is freely movable the fundus will tip backward until it rests on the perineum, but it has presumably been drawn far enough forward so that there is no pressure on the sacrum. The longitudinal axis of the uterus lies across the vaginal outlet, with the cervix, which was formerly the spearhead of the escaping cone, well anchored under the urethra and the fundus resting on the perineum. At this point perineal repair, which is usually necessary, is done by the Mayo method, in order to provide a firm shelf for the posterior wall of the uterus. In one or two cases I have anchored the cervix too far forward, which left it unnecessarily low in the vagina. This difficulty may be largely overcome by placing the sutures farther back under the symphysis pubis.

From an anatomical viewpoint this procedure is peculiar, but it has been useful, and seems to give adequate relief from a trying condition.

DR. JOHN ROCK, Brookline, Massachusetts. Since few women in childbirth entirely escape damage to the pubo-cervical ligament, and cystocele is thus such a common complaint, Dr. Miller has chosen a subject very appropriate for discussion. Since Emmet in the seventies popularized the method of denudation of the vaginal walls and of the development of epithelial flaps, a great deal of water has passed under the arch, so that although the underlying principle of the repair of bladder hernia is still but the application of anatomical knowledge, one now expects the surgeon to understand the art of dissection and reconstruction, and especially, as Dr. Miller points out, to discriminate in the choice of which anatomic factors to utilize. He properly reminds us that suspension of the uterus will not by itself hold the bladder out of the vagina. When herniation of the bladder occurs it is not because its uterine attachment has descended, but because fascial support between the cervix and the symphysis has been weakened. For a permanent cure, reconstruction of this support is necessary.

Dr. Miller warns against repairing the anterior wall and a complete perineal tear at the same time. At the Free Hospital for Women it is customary to repair both simultaneously, since we have no appreciable trouble from breakdown of the anterior plastic, even when the posterior wound has suppurated. Dr. Frank A. Pemberton, following the late Dr. William P. Graves, emphasizes the importance of careful hemostasis, as well as the necessity in all plastic work, of tying all sutures without great tension,

for he believes that breakdown of a wound in the vagina is likely to result from retained blood clot and the cutting through of sutures

The Watkins interposition operation has never been a favorite with us. We seem to obtain equally good results in the repair of large cystoceles associated with normal uteri, with or without elongated cervixes, by advancement and reefing of the bladder, reconstruction of the pubocervical ligament and amputation of the cervix if necessary, without the gross interference with normal anatomy which the interposition operation entails. Like others, we have found that abdominal suspension of the uterus is unnecessary if such repair is accomplished below, unless there be prolapse or symptoms of retroversion. If the cystocele is accompanied by prolapse of the normal uterus, the latter is relieved by approximation of the cardinal ligaments in the midline, which shortens them and thus lifts the uterus—the so-called Fothergill or Manchester technic. Such a procedure is commonly expected to interfere with a subsequent delivery from below, so that in certain women it may properly be accompanied by ligation and transection of the tubes, a comparatively simple adjunctive procedure when done after advancement of the bladder and before reconstruction of the pubocervical ligament.

Dr. Miller emphasizes the importance of careful routine search for enterocele, which so often accompanies prolapse. If present the sac is developed and excised, the stump being attached to the posterior wall of the cervix, provided this has not been removed. If complete hysterectomy has been performed, the stump, together with the uterosacral ligaments, is attached to the base of the broad ligaments. For procidentia we do a vaginal hysterectomy or a Fothergill operation, or a colpocleisis, as seems indicated by the degree of prolapse, the condition of the uterus and the age and condition of the patient.

In all our cystocele operations, exposure and approximation of the subepithelial tissue is carried well forward and laterally to include the region under the neck of the bladder, in accordance with the teaching of Kelly, and later of Kennedy, that support here is essential for the relief of incontinence.

I have never excised redundant vaginal epithelium from above in the course of a complete hysterectomy. When hysterectomy is contemplated, vaginal examination under anesthesia is made, as it is before every abdominal operation, and we believe that the relaxation of the vagina and the cystocele can be diagnosed more accurately and be repaired more safely from below, before the abdomen is opened.

In agreeing as to the value of the Le Fort operation in elderly women, I should like to mention also the advantage of local anesthesia combined with morphine and scopolamine in suitable subjects. At the Free Hospital lately four operations in women over eighty and many others in slightly younger women have been easily and smoothly done, with no complications and with good results.

I am grateful for this opportunity to emphasize Dr. Miller's advice that varying anatomic and pathologic conditions necessitate various operative procedures, and that the surgeon when applying them must be ever aware both of the physiology of bladder control and of subsequent demands on the vagina.

DR. JOE V. MEIGS, Boston. Ten years ago I operated on a girl with a fibroid. As she had a moderate endocervicitis I cauterized the cervix. Seven years later she came back with cancer of the cervix. Four years ago I operated

on another woman with abnormal uterine bleeding, cauterized the cervix and removed the uterus supravaginally, three years later she developed cancer of the cervix. Both patients are dead, but both would be alive if total hysterectomies had been done. I have no faith in cauterization of the cervix as a prophylaxis against cancer. Since then I have leaned more toward total hysterectomy. I formerly endeavored to use Schiller's test and the colposcope to determine when the cervix was dangerous and when it was not, but without complete success. Now if I see what I think is a dangerous cervix, I remove it. If a patient with such a cervix needs abdominal surgery, I believe that a total hysterectomy should be done.

I have puzzled about the repair of a cystocele when doing a total hysterectomy. I had found that on dissecting the bladder free in front of the uterus I ran into the sutures I had used below in the repair of the cystocele, so I discarded that method. It is easy to remove a sufficient amount of anterior vaginal wall from inside to cure the cystocele, as the vagina is pushed off the bladder wall as large a piece as is needed can be removed. When the patient is turned around into lithotomy position it is obvious that the bladder is held sufficiently high and the cystocele has disappeared. Since first adopting this procedure I have operated on 50 or 60 cases in the same way.

If abdominal surgery is to be done, it should come first, as the major consideration to repair a cystocele or perineum, or amputate or repair a cervix, with consequent loss of blood and consumption of time, followed by an abdominal operation, is an incorrect approach if it can be avoided. Vaginal examination and preparation should precede the abdominal operation, following which the patient is again placed in lithotomy position and the perineum is repaired. Occasionally a urethrocele is denuded and sutured.

In repairing urethroceles by the Kennedy method I have found fine silk sutures a great help, the knots are very small and more sutures can be taken. I have done about 15 repairs in this way, and in no case has a wound broken down or have sutures had to be removed.

DR. THOMAS N. HEPBURN, Hartford, Connecticut. Dr. Miller has asked me to speak of the technic of the operation which he has used for urethral prolapse. This type of urethral prolapse is more than what Dr. Miller referred to as a "mucosal prolapse." It involves the whole urethral wall. When I first saw this condition eighteen years ago in a child five years old, I was at a loss as to how to treat it, because all the literature at that time referred to circumcision as the only possible treatment. The prolapse impressed me, however, as a true sliding hernia, requiring treatment as such.

A suprapubic, prevesical, extraperitoneal incision is made, following which the bladder neck falls away under the exploring finger. It requires no pressure to run the hand down under the symphysis and around the urethra. With the child's legs separated and an assistant looking at the urethra, traction is made on the bladder. The prolapsed urethra is easily pulled back with the bladder traction until the assistant announces that the hernia has disappeared, the bladder is then sutured to the periosteum behind the symphysis. This holds it in perfect position.

I am very thankful to Dr. Miller for having adopted this operation. I have had occasion to do it only four times, and I am sure that if any of you are confronted with the problem of urethral prolapse you will find this a very simple and satisfactory procedure.

DR. OLIVER N. EASTMAN, Burlington, Vermont. There are so many advantages in removing the uterus vaginally

instead of by the abdominal route that I advocate this operation whenever conditions warrant. I wish to describe briefly a procedure which has served me well in the repair of cystocele. I am able to report 300 cases in which I have employed it, and the results have been highly satisfactory.

After the uterus has been removed from below, the lateral uterine supports are approximated in the midline below the closed peritoneal cavity. The redundant mucous membrane is removed from the anterior vaginal wall, well up to the base of the urethra. Two sutures of No 2 chromic catgut, one below the other, are utilized to close the bladder hernia. They pass through the mucosa, catching the pubic fascia, and laterally through the vesicocervical fascia to the anterior portion of the body formed by the union of the lateral uterine supports, catching the vesicocervical fascia on the opposite side and then the mucous membrane opposite the entrance of the suture. If a cul-de-sac hernia is present, similar sutures of a purse string nature pass through mucosa and into the posterior portion of the central body. Lateral sutures pass through the mesial portion of the body and out on the opposite side. These sutures, designated as tension sutures, are allowed to remain lax until the vaginal mucosa and deeper structures are approximated by interrupted sutures. The tension sutures are then drawn moderately snugly, causing the vault of the vagina to assume a high position and effectually closing the space anteriorly and posteriorly to the central body.

In 18 cases in my series the patients were over seventy years of age and the operation was performed with local anesthesia, the tissues being infiltrated with 1 per cent novocain. Senility does not seem to be a deterrent factor, as the results are as good as in younger individuals. As a rule, also, the operation is more easily done because the tissues are less vascular. A retention catheter affords relief from bladder distention and obviates frequent catheterization.

A checkup on most of these cases has shown highly satisfactory postoperative results.

DR. CHARLES LARKIN, Waterbury, Connecticut. Dr. Miller said that in some cases of procidentia it is impossible to perform an interposition operation on account of the large size of the uterus. I venture to suggest that these large uteri may be shrunk to normal size by cauterizing the nabothian cysts or the erosions or eversion of the cervical lips which are so often present, or one may use the method advocated by Dr. John Fallon, of Worcester, to shrink the uterus by inserting well screened radium into the uterine cavity. In about six weeks the uterus shrinks enough to permit this operation.

DR. MILLER (closing). I am not familiar with Dr. Smith's operation, reported by Dr. Woodman, but it recalls a similar one which I recollect as coming from Texas. With regard to not combining the repair of a complete tear with that of a cystocele, I believe that the men at the Free Hospital for Women probably take scrupulous care to obtain a normal flora in the vagina, which after all is the essential thing. The interposition operation is possibly finding less and less place. I certainly have found it so, but there are some occasions where with moderate incontinence it is a quick way out of the difficulty.

Dr. Meigs emphasized the importance of doing the abdominal surgery first. That certainly is one of the most important things brought out by this discussion. My paper did not concern itself with the ordinary type of cystocele and prolapse, but dwelt on some of the abnormal features which make us alter our technic, the need for doing the abdominal surgery first is one of these.

I should like to emphasize what Dr. Hepburn pointed out—that the dissection behind the symphysis is extremely easy. In this type of operation it is surprising to find that there is absolutely no supporting connection between the urethra and the symphysis. The bladder neck falls away as soon as the superficial tissues are separated.

## REPORT ON MEDICAL PROGRESS

## THE FAT-SOLUBLE VITAMINS\*

ARNOLD P MEIKLEJOHN, B.M†

BOSTON

THE object of this article is to summarize contemporary knowledge of the fat-soluble vitamins, emphasizing particularly the facts of most interest to practicing physicians. To achieve this in a short space, it has been necessary to eliminate historical and bibliographical details, and to curtail discussion of controversial questions. For more complete treatment the reader is referred to the papers and reviews listed at the end of this article, and particularly to the series of articles which have appeared in the *Journal of the American Medical Association* during 1938. A similar article, dealing with the water-soluble vitamins, will appear subsequently.

## VITAMIN A

**Chemistry** Vitamin A has been isolated in chemically pure state, and its successful synthesis has been reported recently.<sup>1</sup> It is an unsaturated alcohol with the formula  $C_{20}H_{20}OH$ , and is a colorless compound chemically related to the carotenoids, a class of pigments widely distributed in plant tissues. Four of these pigments can be converted by the animal body into vitamin A, and are therefore called provitamins. The commonest and most important of these provitamins is  $\beta$  carotene.

**Physiology** Vitamin A is absorbed in the intestine, passes into the blood stream via the thoracic duct and is stored in the liver. Carotene probably requires the presence of bile salts and fatty acids for its absorption. It passes directly into the blood stream and is taken up by the liver, where it is converted into vitamin A. Vitamin A is an essential constituent of visual purple (rhodopsin), a pigment found in the rods of the retina. Visual purple is necessary for the normal function of the rods in the appreciation of dim light.<sup>2</sup> Nothing is known of the biochemical action of vitamin A in other tissues.

**Pathology** Vitamin A deficiency in laboratory animals is characterized by a morphologic disturbance of epithelial surfaces. The primary change is atrophy of the epithelium, followed by proliferation of the basal cells, resulting in the replacement of normal epithelium by a stratified keratin-

ized layer resembling epidermis.<sup>3</sup> In the bronchial tree this lesion may block the small bronchi with epithelial plugs and give rise to localized bronchiectasis, atelectasis and, frequently, patchy pneumonia. In the cornea of the eye, xerophthalmia results, though generally late in the course of the deficiency. Similar changes can occur in the ducts of glands and in the urinary and genital organs. In the pelvis of the kidney this may predispose to the development of renal calculi, which sometimes occur in animals deficient in vitamin A. There is no general agreement however that calculus formation is a specific effect of vitamin A deficiency.<sup>4</sup> The normal development of teeth is also impaired by vitamin A deficiency.<sup>5</sup> While it has been reported that demyelination of the spinal cord and peripheral nerves can occur in deficient animals,<sup>6</sup> not all workers have found such lesions.<sup>7</sup> Growth is restricted in young animals suffering from vitamin A deficiency, but this is no more a specific effect than the lack of growth that occurs in deficiency of many other essential dietary constituents—other vitamins, essential amino acids and mineral salts.

Epithelial metaplasia similar to that found in animals may occur in man as a result of vitamin A deficiency. Xerophthalmia, though rare and a sign of severe deficiency, has been reported in this country.<sup>8</sup> Children with xerophthalmia succumb very easily to respiratory infections.<sup>9</sup> Skin changes, characterized by hyperkeratosis and absence of sweating, sometimes occur.<sup>10</sup>

Probably the most important effect of mild vitamin A deficiency is night blindness (hemeralopia). Subnormal dark adaptation can be detected with a photometer, and frequently occurs in apparently healthy people.<sup>11</sup> While there are certain difficulties in accepting photometer readings as a definite criterion of vitamin A nutrition,<sup>12</sup> there is no doubt that vitamin A therapy may result in striking improvement of subnormal dark adaptation. The importance of nutritional hemeralopia in automobile drivers has been stressed recently.<sup>13</sup> "Glare-blindness" (nyctalopia), occurring after exposure to bright headlights, may also be due to vitamin A deficiency.

**Assay and Units** The vitamin A content of biologic substances is estimated by feeding tests on growing rats, by a color reaction with antimony trichloride or by spectrometry.<sup>14</sup> The last is prob-

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard Medical School.

†Francis Weld Peabody Fellow, Harvard Medical School, assistant in medicine, Second and Fourth Medical Services (Harvard), Boston City Hospital.

ably the most accurate method. Feeding tests measure the total vitamin A activity (both vitamin and provitamin). The other methods measure only the vitamin, although the spectrometric method can be utilized to estimate carotenoids separately. Depending on which method is employed, different units are currently in use to express the vitamin A potency of foods. The Sherman and international (U.S.P.) units\* are used when the assay has been done by rat feeding tests. Lovibond blue units are used as a standard in the antimony trichloride color reaction, and the readings obtained by spectrometry are converted to international units by the use of a factor. This confusion is made worse by the fact that there is at present no general agreement on how many units of one standard correspond to one unit of another. Probably the best figures at the present time are as follows:<sup>14, 15</sup> 1 Sherman unit is equivalent to 14 international units, 1 blue unit is equivalent to 20 to 30 international units, and the factor most generally used to convert spectrometric readings into international units is 1/1600.

*Sources of Vitamin A and Carotenoids* The most important sources of vitamin A in the human diet are milk, butter, eggs and liver. Carotenoids occur in association with chlorophyll and are therefore present in green vegetables, but not in the pale lettuce leaves which make up the ordinary salad. Carrots and sweet potatoes are good sources of carotenoids and derive their color from them. While color is an index of the provitamin content of milk and eggs, it is not a measure of the amount of the colorless vitamin present in these foods. Canning and cooking do not seem to alter the vitamin A activity of foods.

When it is necessary to supplement the diet with some more potent preparations, fish-liver oils should be used. Cod-liver oil is the most familiar preparation. The U.S.P. dose for infants is 1 teaspoonful (4 cc), and for adults 2 teaspoonfuls (8 cc) daily. The latter amount contains from 5000 to 10,000 IU (international units). Halibut-liver oil has usually from fifty to one hundred times the potency of cod-liver oil. The recognized dose (N.N.R.) for infants is 6 to 10 drops (0.15 to 0.25 cc) daily. A suitable dose for adults is 10 to 20 drops (0.25 to 0.50 cc) daily, it has the advantage that it can be taken easily by patients who find cod-liver oil unpalatable. In most cases, cod-liver oil is preferable, since cases of vitamin A deficiency may also be deficient in vitamin D, and cod-liver oil contains more vitamin D per dose than does halibut-liver oil. Furthermore the additional animal fat has nutritive value. In cases of severe de-

ficiency, amounts considerably larger than the official dose may be given with safety.

*Human Requirements* The probable minimum requirement of an average man is about 2000 IU a day, but due to variation in human weight and activity and in the vitamin content of foods, it is suggested that 3000 IU daily provides a safer margin in calculating dietary allowances.<sup>16</sup> This amount is obtained by the daily consumption of two glasses (500 cc) of milk, one egg, three pats of butter (30 gm) and a moderate helping of green vegetables.<sup>17</sup> Children probably require at least as much as adults. Infants will receive sufficient vitamin A if they are given cod-liver oil in the amounts recommended in the subsequent section on vitamin D.

*Therapeutic Uses* Vitamin A therapy is essential in cases of severe deficiency with xerophthalmia and skin lesions. Patients who complain of night blindness or in whom photometer tests show an abnormal dark adaptation should receive a diet rich in vitamin A, and if necessary additional supplements of the vitamin in the form of cod-liver or halibut-liver oil. In cases of infection, particularly of the respiratory tract, attention should be paid to the dietary history, and if this seems to indicate that the vitamin A intake has been low, additional vitamin should be given. It is a commonplace that ill-nourished individuals withstand infection poorly, and though it is by no means certain to what extent vitamin A deficiency usually contributes to this lowered immunity, its possible influence should not be overlooked. In pregnancy, additional vitamin A may be beneficial. A quart of milk a day supplemented by two teaspoonfuls (8 cc) cod-liver oil may be recommended as an addition to the usual diet. There is some evidence that additional vitamin A during pregnancy may reduce the incidence of puerperal infection,<sup>18</sup> although other more important factors are probably concerned. In addition it may possibly ensure that the colostrum and first milk is well supplied with the vitamin, this may be important in view of the fact that the livers of newborn babies contain very little vitamin A. Care should be taken to provide for an adequate vitamin A consumption in patients with a limited food intake from whatever cause. Vitamin A absorption is probably impaired in steatorrhea, and in liver diseases the storage of vitamin A may be disturbed, such cases possibly benefit by receiving additional amounts of the vitamin.

There is no good evidence that an excess of vitamin A in the diet of an individual already well supplied will lead to any increased immunity to infection. Its use as a prophylactic against colds

\*One international or U.S.P. unit is defined as having the biologic activity of 0.6 micrograms of pure  $\beta$  carotene.

and influenza has no justification if the diet is adequate. It is doubtful whether vitamin A supplements have any beneficial effect in thyrotoxicosis, demyelination of the spinal cord, sexual disturbances or anemia.<sup>4</sup> It is probably ineffective in the treatment of urinary calculi<sup>18</sup> and in the local treatment of skin lesions.<sup>4</sup>

#### VITAMIN D

**Chemistry** Vitamin D is not a single chemical entity, there are a number of known compounds which show vitamin D activity.<sup>20</sup> They are all sterols or steroids, and therefore chemically related to cholesterol and the sex hormones. Probably only two have practical importance. These are calciferol (vitamin D<sub>2</sub>) and vitamin D<sub>3</sub>.<sup>\*</sup> These substances are formed from inactive provitamins by the action of ultraviolet light. The provitamin of calciferol is ergosterol, a substance found in yeast and fungi, but not in ordinary human diets. The provitamin of vitamin D<sub>3</sub> is 7-dehydrocholesterol, which is present in animal fats, liver, milk and butter. The conversion of provitamin to vitamin can take place in the human body if the skin is exposed to sunlight or to rays from an ultraviolet lamp.

**Physiology and Pathology** Vitamin D controls the retention of calcium and phosphorus in the body. Deficiency of the vitamin increases the amount of calcium and phosphorus lost in the feces, and may decrease the concentration of these elements in the blood. In infants the following pathologic changes result: the deposition of calcium salts at the growing points of the long bones is delayed, and the amount of cartilage and osteoid tissue between epiphysis and diaphysis increases, the bones are deficient in calcium salts, and the development of teeth is impaired.<sup>21</sup> The changes are responsible for the characteristic deformities of rickets. Another feature of rickets is hypotonia, which may be manifested clinically by a protuberant abdomen and a delay in learning to walk. The level of phosphorus in the blood serum is usually reduced in active rickets—from the normal level of about 5 mg per 100 cc to 3.5 mg or less. The serum calcium may also be reduced below the normal level (10 mg per 100 cc.), and in such cases tetany is frequent. In adult women vitamin D deficiency may result in osteomalacia,<sup>22</sup> particularly at the time of pregnancy.

Other factors besides the dietary intake of vitamin D may influence the retention of calcium and phosphorus.<sup>21</sup> Not only must the diet contain

Since calciferol, vitamin D<sub>2</sub>, and other known members of the vitamin D group have apparently identical biologic properties, it is possible for practical purposes to consider vitamin D as a single entity.

adequate amounts of these elements, but there should be a proper balance between the amounts of each ingested. This may become important if the diet is restricted to certain foods and does not include milk. (Milk is a good source of calcium and phosphate in balanced amounts.) It is also important that the phosphates in the diet should be in a form that is readily absorbed, which is probably not the case when cereals are the main source of phosphates.<sup>23</sup> An acid-ash diet—rich in meat and cereals, poor in fruit and vegetables—may increase the loss of calcium in the urine. Finally the absence of sunlight prevents the activation of provitamin in the body and increases the need for active vitamin D in the diet.

**Sources** It is a remarkable fact that most articles of human diet are poor in active vitamin D. The best sources are milk, butter, liver and eggs. A pint of summer milk ordinarily contains about 10 units,\* a pat of butter (10 gm) about 8 units, and one egg 20 to 60 units.<sup>24</sup> For therapeutic purposes very much richer sources of the vitamin are required. A great number of preparations containing concentrated vitamin D are now obtainable. Only the better known preparations will be mentioned here, but others may be used in appropriate doses. Cod-liver oil usually contains about 400 units per teaspoonful. It has the following advantages: it is cheap and safe, its fat content has nutritive value, and it may be more effective unit for unit than viosterol. Disadvantages are its fishy taste and the danger of lipid pneumonia if it is vomited and inhaled. If cod-liver oil is not tolerated by the patient a more concentrated preparation may be used, such as tuna oil or viosterol in oil (preferably in oil which also contains vitamin A). Viosterol is obtained by ultraviolet irradiation of ergosterol derived from yeast. It is sold in concentrated oily solution, of which one drop contains 166 units.

Another way of giving additional vitamin D is in vitamin D milk. Three kinds are obtainable. Irradiated milk is standardized to contain 135 units per quart. Metabolized milk (obtained from cows fed with irradiated yeast) and fortified milk (milk to which vitamin D has been added) both contain 400 units per quart.

**Requirements** The amount of vitamin D required by infants is probably variable, but in general it can be said that about 400 units a day are necessary to ensure against the onset of rickets and to promote optimum skeletal growth and dentition.<sup>25</sup> It is clearly impossible for an infant to obtain this amount from milk alone, and for this

\*Vitamin D activity is measured in international (U.S.P.) units. One unit corresponds to the activity of 0.025 micrograms of pure crystalline vitamin D.

reason all infants should be provided with some additional source of the vitamin. There are many different ways of making this provision. One procedure is to start in the first few weeks of life with  $\frac{1}{2}$  teaspoonful (2 cc) of cod-liver oil (200 units of vitamin D) daily, and to increase this after some days to 1 or even 2 teaspoonfuls (4 or 8 cc, 400 or 800 units) a day. This daily dose should be maintained for the first two years at least, and preferably longer.<sup>24</sup> The need for the vitamin may be less in summer, but it is unwise to break the habit of taking the oil regularly when once it is well established. Premature infants require more vitamin D than full-term infants and should receive at least 800 units a day, preferably in some more concentrated preparation than cod-liver oil.

Little is known about the vitamin D requirements in childhood and adolescence, but a teaspoonful of cod-liver oil a day might reduce the incidence of dental caries, and promote optimum growth in children who are rarely exposed to the sun or whose diet lacks abundance of milk and butter.

Nothing is known about the vitamin D requirements of adults. It has been suggested that additional vitamin may be beneficial in the following types of cases: people kept from the sunlight for long periods, particularly bed-ridden invalids in whom the bones are becoming rarefied, patients recovering from fractures, and individuals with a poor dietary history, particularly if no milk—the main dietary source of calcium—has been taken.<sup>24</sup> Pregnant women should receive at least 800 units a day throughout pregnancy, together with a liberal supply of milk.

**Therapy.** In the treatment of rickets a good procedure is to start with three teaspoonfuls (12 cc) of cod-liver oil (1200 units of vitamin D) daily, and to increase the dose if no improvement is evident after one month.<sup>24</sup> X-rays are useful in demonstrating the effect of treatment on bone formation at the growing points. Refractory cases of rickets that require relatively enormous doses<sup>25</sup> are occasionally encountered. In treating such cases care must be taken to avoid overdosage, which results in gastrointestinal symptoms and supranormal levels of calcium in the blood. Metastatic calcification may occur in the arteries and elsewhere, with serious consequences.

Vitamin D therapy has been recommended in a variety of conditions apparently unrelated to vitamin D deficiency. More work appears to be needed before these recommendations can be generally accepted.

Finally it should be emphasized that an ade-

quate intake of vitamin D is not alone sufficient to ensure normal retention of calcium and phosphorus. The diet must also contain an adequate supply of these elements, and this is most easily provided by the regular consumption of milk or cheese.

#### VITAMIN E

The vitamin E activity of biologic materials is due to a group of chemical substances known as tocopherols. They are found in vegetable oils, particularly in wheat-germ oil. Vitamin E deficiency in rats results in sterility in the male, and resorption of the fetus in the female.<sup>27</sup> Nothing is known about the human requirements for vitamin E. There have been some reports suggesting that wheat-germ oil may be useful in the treatment of habitual abortion.<sup>28</sup>

#### VITAMIN K

Vitamin K is a fat-soluble substance found in a variety of foods. The best-known sources are alfalfa and decayed fish meal. Fowls deficient in this vitamin develop hemorrhages, which are probably due to a lack of prothrombin in the blood. Human cases of obstructive jaundice with a bleeding tendency may show an abnormally long prothrombin clotting time.<sup>29</sup> It has been recently suggested that this is due to failure to absorb vitamin K, in the absence of bile secretion. This hypothesis is supported by the observation that vitamin K taken with bile salts by mouth may improve the prothrombin clotting time in some cases of obstructive jaundice<sup>30</sup> and that vitamin K has been found to have the same effect in a few cases when given by intramuscular injection.<sup>31</sup>

#### CONCLUSIONS

An ample diet, well supplied with dairy products, provides sufficient fat-soluble vitamins for the needs of the normal individual, except during infancy, pregnancy and lactation. Deficiency of fat-soluble vitamins is liable to arise when the diet is restricted, particularly in infants and children who do not receive enough milk. Fish-liver oils correct such deficiencies but do not compensate for the lack of other essential dietary constituents supplied by milk.

TRACY B. MALLORY, M.D., *Editor*

### CASE 25021

#### PRESENTATION OF CASE

A seventy-seven-year-old, white, married man entered complaining of paroxysmal dyspnea, disorientation and generalized fibrillary muscle twitchings of four days' duration.

Approximately five years before entry the patient was admitted for a right inguinal hernia, constipation and a trace of glycosuria found in only one specimen. He drank rather large amounts of water and had nocturia several times each night. Walking caused his legs to ache. The previous year he had had sudden pain and swelling in the left foot. It remained colder than the other, with occasional slight swelling. His arteries were palpable and tortuous, his extremities cold and cyanotic. Examination of the heart at that time showed a rate of 48, with frequent dropped beats. There seemed to be slight enlargement to the left. No murmurs were heard.  $A_2$  was louder than  $P_2$ . The heart sounds were of good quality. The blood pressure was 130 systolic, 80 diastolic. The lungs were clear. Simple therapeutic measures gave marked relief of most of his symptoms, and he was discharged.

Six weeks before entry he had had an attack of precordial pain and accompanying symptoms which his physician thought were due to coronary occlusion, but a series of electrocardiograms did not substantiate such a diagnosis. It was therefore decided that there was coronary sclerosis, probably without definite occlusion. Pulmonary rales appeared shortly thereafter, and there was questionable ankle edema. Digitalization gave relief, and there was definite improvement although the patient failed to regain his previous state of health. About four days before entry he developed Cheyne-Stokes type of respiration, apparent air hunger with paroxysmal dyspnea, disorientation and generalized muscle twitchings. He had lost 25 pounds in weight during the past year. There were occasional twinges of precordial pain. Extrasystoles had been noted from time to time.

Physical examination on entry showed a disoriented, moderately ill man with Cheyne-Stokes breathing. The skin and mucous membranes

were dry but not discolored. The pupils were equal but reacted sluggishly to light. There was 3 to 4 cm of dullness at the right base, and diminished breath sounds. Crackling rales were heard over both right and left lower lung fields. The heart rate was 100 and regular except for ventricular premature beats. There was a suggestion of early gallop, the sounds being of poor quality. No murmurs were heard.  $P_2$  was greater than  $A_2$ . The left border was 12 cm to the left of the midline. The blood pressure was 130 systolic, 100 diastolic. Examination of the abdomen was negative except for an easily reducible right inguinal hernia. Knee jerks and ankle jerks could not be obtained. There was no clonus. Babinski signs were equivocal. Numerous muscular twitchings were noted over the entire body, but no weakness or sensory impairment was elicited.

The temperature was 96.8°F., the pulse 100, the respirations 40.

Examination of the urine showed a specific gravity of 1.033, a slight trace of albumin, a rare red cell and 8 white cells per high-power field, no sugar and no diacetic acid. The blood showed a red-cell count of 4,640,000, 80 per cent hemoglobin, and a white-cell count of 13,200 with 86 per cent polymorphonuclears. The nonprotein nitrogen of the blood serum was 39 mg per cent.

An x-ray film of the chest showed soft mottled dullness throughout the lower third of each lung field. On the left the shadow was most dense near the hilus, on the right at the extreme base. The heart shadow was indistinctly seen through the dull area and appeared to be only slightly enlarged. The apices were clear.

An electrocardiogram showed that  $T_1$  and  $T_2$  had become low compared with the record taken six weeks before entry.  $T_4$  had changed in contour. The changes were in the direction of normal, although the T waves remained abnormal. The P-R interval was 0.18 second. The ventricular rate was 100, the auricular rate 100.

On the day after admission the patient's condition was worse. There was slight cyanosis of the lips and nails. The pulse rate was 110 to 120. Respirations were of a more accentuated Cheyne-Stokes character. However, he seemed less irrational. On the third hospital day neurological examination showed a suggestion of spasticity in the left leg, with occasional doubtfully positive Babinski and Chaddock signs. There was left facial weakness, and slight drooping of the left eye. The patient was incontinent. He muttered half-formed words and did not recognize the examiner. The following day he was still delirious but complained of an intermittent mildly irri-

tating discomfort in the left anterior chest, which was aggravated by breathing. He had an abortive coughing grunt in paroxysms at long intervals, but no expectoration. Physical examination was unchanged except that the left facial weakness was more marked, the leg signs had disappeared and the patient was rational for a few minutes.

On the fifth day he was up in a wheel chair. In the late afternoon he had occasional chilly sensations lasting about twenty minutes, followed by profuse sweating, but his temperature remained at 98°F. His pulse was 120, the blood pressure 100 systolic, 65 diastolic. On the sixth day the facial paresis had disappeared. His general motility had improved bilaterally but there seemed to be less motion on the left. There was otherwise no change. On the ninth hospital day he was still confused. He had some difficulty in swallowing orange juice. Twitchings were still noted in the face, tongue and extremities. The heart was regular, with a rate of 108, gallop rhythm and sounds of poor quality. Rales remained at both bases. The left face was slightly weaker than the right. On the eleventh day rales were heard in the left back and axilla, with a few at the right base. The serum nonprotein nitrogen was 31 mg per cent, the red-blood-cell count 4,800,000, the white-blood-cell count 14,100, and the temperature 96°F. On the fourteenth day he was sitting in a chair without apparent shortness of breath and without Cheyne-Stokes respiration. He had received aminophyllin for four days, and his output of urine had increased. An electrocardiogram showed lower T waves than in the previous records apparently indicating increased myocardial damage.

There was marked Cheyne-Stokes breathing on the seventeenth day. The pulse was 130 to 140. A chest plate still showed mottled dullness in both lower lung fields, with no appreciable change since the last film. On the twentieth day there was slight edema of the back, and many rales in the left back and axilla. His condition seemed somewhat worse. The heart sounds were faint at a rate of 96 but fairly regular. His blood pressure could not be determined accurately, the systolic pressure was 95 to 100, the diastolic indefinite. The following day he showed a leaden pallor and was obviously running a downhill course. His urine output was decreasing, and edema increasing. The serum nonprotein-nitrogen was 109 mg per cent. He continued to complain of pain in the left chest and could not lie on that side. The left arm was more swollen than the right. He became gradually weaker but passed a peaceful night. The

following morning he gave a single gasp and died.

#### DIFFERENTIAL DIAGNOSIS

DR HOWARD B SPRAGUE At first this case seems fairly straightforward, but there are a few factors that do not seem to fit into the diagnosis suggested by the history. His first admission can be summarized by saying that at the age of seventy-two he was examined and showed evidence of general arteriosclerosis, perhaps with a mild sclerotic diabetes. He had a history suggesting an occlusive episode in an artery of the foot. When they say his heart had a rate of 48 with frequent dropped beats, I suppose they refer to what was felt at the wrist rather than at the apex of the heart. He probably had premature beats that did not reach the wrist rather than heart block, because five years later, at the age of seventy-seven, he did not show heart block. His heart otherwise did not seem to be particularly involved, being only slightly enlarged, and he had a normal blood pressure, no heart murmurs and a good quality of heart sounds. Then we know nothing about him until six weeks before he entered the hospital, when he had an attack of precordial pain, from which he apparently never recovered to any appreciable extent, and developed a picture of congestive heart failure.

Precordial pain is not the type of pain that is ordinarily described in coronary occlusion although I have seen it with a proved diagnosis of occlusion. If he did not have a coronary attack at that time we have to think of pain of pericardial disease or pleural disease or some other pulmonary or mediastinal pain. We have no pleural or pericardial rub described. There is nothing to suggest that he had a dissecting aneurysm, either on physical examination or by x-ray, and in the absence of hypertension, that would seem to be unlikely. The findings then are congestive failure, with the congestion localized in the bases of his lungs.

Paroxysmal dyspnea and Cheyne-Stokes breathing are commonly seen in arteriosclerotic individuals with cardiac failure. He had lost 25 pounds in weight. Can we ascribe that to the arteriosclerosis, which often does result in loss of weight, or should we think of cancer? The heart examination on his second visit showed an increase in size, murmurs were still absent but there was a change in the heart sounds as they were of poor quality and there was a suggestion of gallop rhythm. The blood pressure had not been disturbed unless he had had some hypertension in the interim. The neurologic signs and generalized muscular twitchings do not mean very much to me. At his age, I

believe that very ill individuals can have general fibrillary twitchings over the entire body without its meaning a primary neuromuscular condition. His urinary examination at that time does not suggest that he had much impairment of function on a primary nephritic basis but a certain amount secondary to congestive heart failure.

DR. AUBREY O. HAMPTON: I am going to add the postmortem films in this case because they are of better quality. The first portable examination of the chest showed a relatively dense left mid-lung field and an obscured left side of the diaphragm, with a clear space between the lower and middle shadows. On the right side a rather dense shadow which runs irregularly downward along the heart shadow is seen, and this is fairly sharp in lateral outline. You do not see the diaphragm on either side. The heart is moderately enlarged in spite of the fact that this is a portable film. At the second examination the pulmonary conus, if that is it, is prominent, but the density in the lungs has changed very little. In the post-mortem films the chest appears much clearer than in the antemortem ones. The disease that we might have suspected in the upper lobes is not certain, and all we see is homogeneous density at the right base and an indefinite, ill-defined, rather oval shadow on the left side, which is flat against the posterior chest wall at about the sixth rib. It looks quite a bit like encapsulated fluid, or even tumor can have this appearance. It is very sharp in outline in the lateral view, and it suggests an infarct because of this. The shadow here in the lateral view is along the superior margin of the lower lobe, and you cannot tell from this other view which lobe it is in.

DR. SPRAGUE: It looks from the x-ray films as if this man had died cured. To proceed he ran a downhill course with some changes in the electrocardiogram which were not specific and with neurological signs which were variable and seemed to indicate minor occlusive episodes in the cerebral circulation. The cardiac findings on physical examination were those of falling blood pressure, the poor quality of the heart sounds increasing and gallop rhythm persisting. At the end his non-protein nitrogen was increased to 109 mg per cent, which I believe could be accounted for on the basis of congestive failure. He died rather suddenly.

The joker in the situation seems to be the pulmonary lesion. We must admit, I think, a generalized arteriosclerosis, and with changes in the T waves in the electrocardiogram, we cannot disregard the probability of coronary disease, perhaps of multiple coronary occlusion or a generalized process, without evidence of an acute large in-

farct. Are the changes in the lungs those of congestive heart failure which has been relieved, or are they those of multiple pulmonary infarction or cancer? The lack of progression of this picture is not in favor of cancer but of something which was remediable, and the best guess to my mind is pulmonary infarction, perhaps with some pleuritic response and accumulation of fluid. If these are pulmonary infarcts, it is not necessary to assume that they came from the heart because they may have come from the peripheral venous circulation. My diagnosis is generalized arteriosclerosis including cerebral and coronary sclerosis, with multiple small cardiac infarcts and pulmonary infarcts.

DR. JAMES H. MEANS: I saw this patient over a period of years in my office, and then I saw him in consultation with his local physician at the time of his last illness and cared for him in the hospital. There are a number of points I should like to mention. Dr. Sprague asked about the heart condition back in 1933. I do not know to what that 42 rate was due, or from where that note came. The chart showed a rate of about 60, and the electrocardiogram taken in 1933 reads "Normal rhythm, heart rate of 65, P, Q, R, S and T waves normal in all leads, a tendency to very slight left-axis deviation, well within normal limits. Lead 3 was the unstable lead and varied some with respiration."

During the last illness there were several features which are worth going over. He had about as troublesome Cheyne-Stokes breathing as I have seen. That was the cause of his distress. He would sleep during the apnea and have bad dreams, and then would wake up in terror. Dr. Cobb saw him with me. He might comment on that part of it.

Dr. Sprague has considered the possibility of some unsuspected lesion. So did we. We thought of cancer on account of the weight loss but could not find any evidence and finally concluded he did not have it.

The findings in the left chest are worthy of comment. For the few days before he died he had pain on breathing and I examined the chest carefully. He had an x-ray examination shortly before death which was not very helpful, but I did wonder if he had some queer lesion in the left chest. I did not have the faintest idea what it was, because I could not find any physical signs, but it turned out that there was something peculiar there that we shall hear about later. He also had some swelling of the left arm. The pain in the left chest and arm made one wonder what was going on in the left chest or mediastinum. Of course Dr. Sprague has had the advantage of

postmortem x-ray films which I did not have when I made the following note the day he died I predicted "The pathologist will find a heart only slightly enlarged, if at all, with narrow coronaries and old infarcts. Some degree of fibromyocarditis and general arteriosclerosis will be present and in the main I expect there will be found extensive arteriosclerosis with thrombosis and softening in some silent area of the brain. Slight general anasarca will be present. There will probably be hypostatic pneumonia, not very marked, at each base. I am aware of no other lesion." The mental picture made me think there must be a lesion in the brain, which I presumed was sclerotic in origin.

DR STANLEY COBB I agree absolutely with Dr Means's diagnosis. I might add about the brain that you may often have symptoms like these and at autopsy not have any recognizable lesion in gross, there are hardening of the arteries and areas of relative ischemia, but no areas of softening. On microscopic examination you ought to find a loss or abnormality of the nerve cells in some localized area. That should explain everything except his rather marked muscular twitchings. They were unusual in lasting for a long time. I do not know of anything that explains them satisfactorily, and I suppose we must fall back on the theory of relative ischemia of the brain for a long while, because of the hardening of the arteries.

#### CLINICAL DIAGNOSES

Cardiac infarction, old  
Arteriosclerosis  
Cerebral thrombosis, with softening  
Hypostatic pneumonia

#### DR SPRAGUE'S DIAGNOSES

Arteriosclerotic heart disease, with congestive failure  
Coronary occlusion (probably multiple)  
Multiple pulmonary infarcts  
Minor occlusions of cerebral vessels

#### ANATOMICAL DIAGNOSES

Arteriosclerosis, marked, coronary, cerebral and aortic  
Coronary thrombosis, old and recent  
Aneurysms, arteriosclerotic, right coronary and left internal iliac arteries  
Infarct of heart  
Hypertrophy of heart.  
Pulmonary embolism, with pulmonary infarction  
Bullous emphysema, left lower lobe  
Diffuse cerebral atrophy

#### PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY This man showed a very extensive and diffuse arteriosclerosis. His heart was very much enlarged, weighing 650 gm. It showed severe coronary sclerosis affecting all branches, with two thrombi, a fairly fresh one in the left circumflex artery and an older one in the main right coronary artery. The latter artery was quite unusual in that it showed a fusiform aneurysm 1.2 cm in diameter and 1.5 cm in length which was completely filled with a partially organized thrombus. There was a large area of infarction at the apex and a still unorganized overlying thrombus, which was consistent with a duration of six weeks as suggested by the history. The left auricle contained a mural thrombus which might well have been the source of peripheral emboli but was not, so far as we could discover. The episode of circulatory difficulty in his toe, going back to the earlier admission, was probably explained by an aneurysm of the iliac artery which contained a thrombus, and I imagine that at some earlier period a small embolus broke off from this and was swept down to a small vessel of the foot. The lungs proved interesting. They showed complete infarction of both lower lobes, and on the left the picture was complicated by the fact that there was a huge emphysematous sac which overlaid the infarct. It must have made considerable difference in the physical signs over that area and also served to confuse the x-ray picture. There were multiple pulmonary emboli to correspond with the areas of infarction. The brain showed a severe, rather diffuse arteriosclerosis, with evidence of diffuse atrophy. Perhaps Dr. Kubik will tell us more.

DR CHARLES S. KUBIK The ventricles were twice the normal size, and the convolutions showed atrophy. There was no infarction that one could see with the naked eye.

DR MEANS Just what was the brain lesion?

DR MALLORY A diffuse cerebral atrophy, which I should think was without much question based on severe arteriosclerosis.

DR MEANS Is that the sort of thing that precedes or takes the place of softening?

DR MALLORY The latter I think. Most of the cases in which we have seen such a picture have had pretty diffuse cerebral sclerosis, have they not, Dr. Kubik?

DR KUBIK Yes, one is likely to find numerous small infarcts with the microscope and sometimes can see them with the naked eye. I do not believe there was anything one could see with the naked eye in this case, however.

DR MEANS In regard to the size of the heart, I could not make out any great enlargement on

physical examination and was influenced by the statement of the radiologist that the heart shadow was indistinctly seen through the dull area and appeared to be only slightly enlarged. The patient was too sick for a seven-foot film.

## CASE 25022

### PRESENTATION OF CASE

A seventy-seven-year-old, white, Canadian night watchman entered the hospital with the complaint of vomiting and hematemesis of four weeks' duration.

Seven years before entry he had had a "heart attack" characterized by breathlessness and generalized edema. He remained in bed for three weeks and two weeks later returned to work. He was given digitalis for the first month. He continued to be somewhat dyspneic but was able to work until two years before entry, when he fell, striking his right chest. He stayed in bed for two days but was unable to return to work because of dyspnea and ankle edema. His physician put him on a regime of restricted activity, with digitalis and Salyrgan medication, and he remained fairly well until six months before entry. At that time he suddenly developed pain in the left eye and soon was unable to see with it. For several years the vision in his right eye had been rather dim. Four weeks before entry he had had two episodes of vomiting. The vomitus contained gross blood. However, his appetite and digestion appeared to be unimpaired. Three weeks before entry he had again vomited clots of blood, and this was repeated one week later. During the two weeks before entry his appetite was poor, and his bowel movements were not so regular as they had been previously. During the recent period of his illness he had become pale and had shown some mental disorientation and loss of memory. On two occasions about seven months before entry he had had very severe nosebleeds.

His past history and family history were essentially negative. He had traveled all over the world as a seaman until he was thirty years old. He denied taking any alcohol.

Physical examination revealed a very pale, somewhat dyspneic, emaciated old man, lying flat in bed in no great discomfort. The veins of the neck were distended, and the left eyelid drooped. The lungs showed coarse moist rales at both bases. The heart was very much enlarged to the left, with a harsh systolic murmur heard loudest at the aortic area. The blood pressure was 140 systolic, 90 diastolic, and the pulse had an alternating quality. The liver was enlarged and somewhat tender. The abdomen was

slightly tender throughout, but no masses were felt. The rectal examination was negative. There was pitting edema of the lower legs and feet, and the genitalia were somewhat edematous.

The temperature was 97°F, the pulse 75. The respirations were 20.

The urine had a specific gravity of 1.018 and contained a trace of albumin and occasional casts. The blood showed a red-cell count of 1,200,000 with 22 per cent hemoglobin, and a white-cell count of 11,000 with 78 per cent polymorphonuclears. The guaiac test on the stool was 2+. The nonprotein nitrogen of the blood was 117 mg per cent.

On the second day a transfusion was given, but after 400 cc of blood had been injected the patient began to cough and developed rales in the upper lung fields. He recovered from this and his condition remained about the same until the fourth day when, after exerting himself to sit up, he suddenly fell back, gasped a few times and died.

### DIFFERENTIAL DIAGNOSIS

DR RICHARD J CLARK. We are confronted with an elderly man in the degenerative-disease age group. He had had a history of cardiovascular disease of seven years' duration, apparently with acute congestive heart failure seven years before death. This was followed by temporary improvement and then recurrence of failure, which was slowly progressive, with limitation of activity.

Six months before entry he developed sudden pain in the left eye followed by failure of vision. There is little to indicate just what occurred. It might have been acute glaucoma but more likely was an acute vascular accident, such as an embolus in the central artery or a venous thrombosis.

Four weeks prior to entry we have the onset of his terminal situation of vomiting and hematemesis. The vomitus contained large amounts of blood and clots. With the onset there was no story of nausea, abdominal pain or indigestion. The vomiting was spontaneous and seemed dependent on blood in the stomach. There is no other history of a bleeding diathesis, except for two severe nosebleeds seven months before which may well have resulted from hypertension.

On examination there was evidence of cardiac enlargement and failure. The blood pressure was relatively normal, but we may well assume that it was considerably elevated prior to his cardiac failure and repeated hemorrhages. His liver was enlarged and slightly tender. Apparently no spleen was felt.

The urine showed a good concentration, but

his nonprotein nitrogen was 117 mg per cent. This may represent, in part at least, an extrarenal azotemia dependent on cardiac failure, blood and electrolyte loss and possibly liver disease. There was a profound anemia. We are told nothing about the blood smear, platelets or bleeding time, which helps us little toward a possible diagnosis of primary blood dyscrasia. Therefore we may reasonably assume that this was a severe secondary anemia.

Following transfusion the patient apparently developed acute pulmonary edema. His exodus was probably cardiac, although the possibility of a pulmonary embolus must be entertained.

The chief problem here is that of the cause of the hematemesis. This was gross acute bleeding. It might have come from a gastric or duodenal ulcer, but such repeated bleeding would seem unlikely in the complete absence of other symptoms of such a disorder. With cancer of the stomach the bleeding is more likely to be an oozing, with coffee-grounds vomitus. Acute gastritis should give other symptoms and bleeding in smaller amounts. There is no evidence for a primary blood dyscrasia. Such a massive degree of bleeding from a chronic Bright's disease would be unusual. In an old man with chronic vascular disease the possibility of an aneurysm's rupturing into the esophagus might be considered, but we should expect one profuse fatal hemorrhage with this condition. Why are we told of the blow to the right chest? Could he have developed a traumatic diaphragmatic hernia, with bleeding resulting from this? There are no other symptoms that point in this direction, and I believe such a diagnosis is unlikely.

The most probable cause of this bleeding is from esophageal varices dependent on a portal cirrhosis of the liver. The type of bleeding and the patient's general state fit with this. We should like to have had an alcoholic history, a description of dilated abdominal veins and possibly an enlarged spleen. There was no ascites or jaundice, but this need not deter us from the diagnosis. I may be wrong, the enlarged liver may be one of chronic passive congestion, and the bleeding may depend on passive congestion, with bleeding from an abnormal plexus of veins. However, lacking any x-ray or further data, I shall make a diagnosis of cirrhosis, with esophageal varices.

I believe a very much hypertrophied heart of the hypertensive type with coronary sclerosis will be found. Because of the harsh systolic murmur in the aortic area, calcification of the aortic valve is to be suspected, or possibly marked dilatation of the aorta. There will be acute and chronic pas-

sive congestion, together with generalized arterio sclerosis and also nephrosclerosis.

#### CLINICAL DIAGNOSES

Hypertensive and coronary heart disease with congestive failure  
Chronic vascular nephritis with uremia  
Hematemesis, etiology undetermined  
Secondary anemia  
Generalized arteriosclerosis

#### DR CLARK'S DIAGNOSES

Hypertensive heart disease, with cardiac hypertrophy  
Coronary sclerosis  
Calcification of aortic valve?  
Congestive failure, acute and chronic  
Generalized arteriosclerosis  
Nephrosclerosis  
Portal cirrhosis  
Esophageal varices

#### ANATOMICAL DIAGNOSES

Cardiac hypertrophy, hypertensive type  
Calcification of cusps of aortic valve, slight  
Arteriosclerosis, generalized  
Nephritis, chronic vascular, marked  
Hydrothorax, bilateral  
Chronic passive congestion

#### PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY. This is the type of case that is apt to be a little disappointing, but I think is, nevertheless, worthwhile presenting every once in a while. All Dr Clark's predictions are correct except as regards the cirrhosis of the liver and the cause of the hematemesis. Absolutely nothing was found to explain the latter. We see on the average, one case a year of very severe hematemesis for which we are unable to find a cause. What the explanation of such cases is, I have no idea. It is not inconceivable, I suppose, for a man to have a nosebleed in his sleep and wake up and vomit blood.

He did have a very big heart, weighing 700 gm. He had some calcification of the aortic cusps. There was no real aortic stenosis, however. There was a point omitted in the physical examination that should have been recorded. The aortic second sound was louder than the pulmonic and not diminished as it probably would have been with true aortic stenosis. The lungs showed passive congestion. The kidneys showed rather marked nephrosclerosis and also a very severe cystic degeneration of the type that we see in elderly people—an entirely different type of cyst from that of the congenital polycystic kidney. In these older

people it is easy to prove that the cysts develop from glomerular capsules, presumably because of a blocked tubule. Bowman's capsule gradually dilates, the glomerulus shrinks to smaller and smaller proportions and finally disappears entirely. In the congenital polycystic kidney, the cysts have nothing to do with Bowman's capsule, and their origin is entirely unknown.

DR ALLEN G BRAILEY: Was it an anginal death?

DR MALLORY: He had very good coronary arteries and we cannot assume that it was an anginal death.

DR JOHN D STEWART: How large was the liver?

DR MALLORY: Moderately enlarged, due entirely to chronic passive congestion.

DR JOHN W ZELLER: What was the cause of death?

DR MALLORY: I should say cardiac decompensation and uremia. Why it was sudden, I am not sure, but in a man with chronic nephritis of this type a nonprotein nitrogen of 80 mg per cent is in the uremic level.

DR RICHARD CHUTE: The anemia was secondary to the vomiting of so much blood rather than secondary to the renal condition?

DR MALLORY: It could have been due to either

I have no way of distinguishing. Probably the two were cumulative in their effect.

A PHYSICIAN: Was there any antemortem diagnosis of the eye condition?

DR MALLORY: There is no note. He was in the hospital a short period, and no eye consultant had seen him. We did not have permission to examine it postmortem.

DR BERNARD JACOBSON: Was the bone marrow normal?

DR MALLORY: No, it was hyperplastic so far as the vertebrae were concerned.

DR JACOBSON: It was not suggestive of pernicious anemia?

DR MALLORY: Not in the slightest respect.

DR THORNTON SCOTT: What kind of heart disease did he have?

DR MALLORY: Straight hypertensive heart disease, I should imagine. The kidneys certainly connote hypertension. Clinically we have nothing except a slightly elevated diastolic pressure on the final entry to give evidence, but it is very common in hypertensive disease to have the blood pressure fall terminally.

DR WYMAN RICHARDSON: A blood pressure of 140 systolic, 90 diastolic, is quite high for a man with a red-count of 1,200,000. It is almost hypertension in itself.

DR MALLORY: Yes.

## THE LICENSING OF HOSPITALS

THERE is a widespread conviction that the relation between physician and patient is of such an intimate and personal character that complete governmental control of the practice of medicine is chimerical. But there recurs constantly the question of whether less than complete control should be extended in some specific field of medicine. It is difficult to establish a general principle and to apply it wisely, so that before attempting to solve the problem for any limited field one should endeavor to discover the facts of practice in that field, the abuses, if they exist, the harm resulting and, finally, the remedy or remedies. Comparison with other fields and analogous problems should be made.

The abuses possible in uncontrolled hospitals for patients needing the care of a psychiatrist are too well known to demand a reopening of the question of whether such institutions should be

licensed. In Massachusetts, they have all been placed under the Department of Mental Health, even though they are privately owned.

The need for the protection of women during childbirth has been recognized formally to the extent of requiring a license from the Massachusetts Department of Public Welfare for an institution which cares for such patients. Infants and children can no longer be "farmed out" as formerly, and the Commonwealth carefully supervises certain aspects of the care of these wards.

In the case of surgery, however, there is almost no supervision other than that the hospital building must meet the regulations of the local fire department. The most serious defect is that any physician licensed by the Board of Registration in Medicine may practice surgery. The candidate may be a psychiatrist of thirty years' practice, who has never seen an operation since he left the medical school. Or he may be a neophyte, just graduated from medical school, who has never actually participated in an operation and who failed miserably in the examination in surgery given by the Board, but whose general average was at the passing level. Both alike are free to operate if they see fit.

What may such a physician do? He may rent a small dwelling house for a hospital, employ a nurse, registered or unregistered, who will be superintendent, head nurse in the operating room and first assistant at all operations, another nurse, registered or unregistered, who will be night supervisor and extra nurse in the operating room, and a general-duty domestic servant, who will also cook. The surgeon may use some non-inhalation form of anesthesia and then perform abdominal operations, such as removal of the appendix, without the assistance of another physician. He may make, or fail to make, such records as he sees fit. He may falsify records and diagnoses and causes of death. He may have a showy array of therapeutic and laboratory apparatus and he may go through the gestures of making applications and examinations and writing down suitable results, which are impressively gone over with the patient's family, especially if death ensues, as indicating that everything humanly possible was done. If by chance

the physician is a clever operator, a clever salesman and a clever rascal who knows how to cover his tracks, what is the likelihood of his being discovered?

If by chance the physician is an abortionist who keeps careful and minutely detailed falsified records of examinations which indicate that the patient was not pregnant, even to a negative Aschheim-Zondek test and a notation that the doctor told the patient that she was not pregnant, and if the patient leaves the hospital in five or six days, satisfied, is there any likelihood of detection?

If the surgeon operates without consultation, never benefiting by the opinion of a pathologist, destroying without record or with falsified record, all tissue removed at operation, he may perform an enormous number of unnecessary operations and do untold harm. Thus, the unscrupulous and clever surgeon constitutes one of the most serious menaces in the care of the sick. Conscience and fiduciary responsibility are for him non-existent.

There arises also the question of whether all hospitals should be licensed, not merely those in which surgical operations are performed. Practically, the separation of hospitals into two such groups is impossible. Surgery should be regarded merely as one method of therapy. Pneumonia or typhoid fever or any one of a number of other medical diseases may develop complications demanding surgical treatment. To attempt to move the patient to another hospital might prove fatal and certainly would be dangerous.

For the improvement of medical care all hospitals should be licensed and all surgery should be checked in such a way that it is a matter of record that a definite diagnosis was made, that treatment was carried out by competent persons under reasonably satisfactory conditions for good surgery, that certain conditions were found at operation and that all tissue removed was examined in the laboratory by a competent pathologist.

In all first-class hospitals these have been among the minimum requirements for years, and the public has no conception of how much benefit it has received from the standardization of hospitals which, under the auspices of private agencies, has

made such progress in the last quarter of a century. Now that private initiative has shown the way, public control by licensing of all hospitals may justly be required for the protection of the public. The members of the medical profession, who know not only the possibilities for abuse but also the actual abuses, should lead the way in advocating this necessary advance.

---

## PHYSIOLOGICAL RESEARCH

THE lecture by Professor Meyerhof on the chemistry of the anaerobic recovery of muscle, which appears in this issue of the *Journal*, is an outstanding example of sustained and integrated physiological research. Its interest to the physician does not depend on a complete understanding of the complex chemical reactions that are discussed. What will appeal to the physician is the bird's-eye view of the nicety with which chemical and physical in vitro experiments have been correlated with the changes occurring in the physiologic processes of functioning tissue. The physician appreciates that the practical application of this knowledge to human subjects has already advanced our understanding of the physiology of exercise. He knows that the muscular dystrophies and diabetes mellitus involve deranged metabolism of creatine, phosphates, lactic acid and glucose. But the work reviewed by Professor Meyerhof shows that muscular metabolism not only involves these familiar compounds, but also depends on a whole new group of active intermediary products. These substances, which appear, split up and are resynthesized, are essential to muscular activity. Their discovery is as fundamental as that of the hormones or the vitamins. This new knowledge is particularly important to the physician, who continually attempts to comprehend and control various aspects of cellular activity in patients.

As the physician thinks of patients with perhaps a better understanding of these new factors he may see new ways of attacking clinical problems. Indeed, his clinical material may provide him with means of extending the knowledge of the physiologist that might never come to the latter's attention.

## PLACENTA ACCRETA

The patient was a thirty-eight-year-old primigravida, whose last menstrual period began April 14, 1937, and who was due to be confined January 21, 1938. When first seen, at seventeen weeks, her uterus was considerably larger than it should have been on the basis of her dates. Her pregnancy was uneventful until one week from term, when she had an elevation of blood pressure to 150 systolic, 100 diastolic, at which time her ankles were swollen and her urine showed a trace of albumin. Late in pregnancy a 5-cm uterine mass, probably a fibroid, was palpated to the left and below the umbilicus.

Although labor pains began January 23, she did not begin to show dilatation of the cervix until four days later. The next day the membranes ruptured spontaneously and twenty-four hours later an infant, weighing 8 pounds, 10 ounces, was delivered following a lateral episiotomy. The placenta failed to separate, and so the patient was returned to her room. There was no external bleeding or evidence of accumulation of blood in the uterus. The latter reached nearly to the right costal margin and revealed another 5-cm mass, this one attached to the fundus. After fourteen hours of failure of the placenta to separate, the patient was prepared for exploration of the uterus, a diagnosis of placenta accreta having been made. She was in good condition, with a blood pressure of 140 systolic, 84 diastolic, and a pulse of 96 to 124. Under nitrous oxide, oxygen and ether anesthesia the vulva and vagina were prepared with mercurochrome acetone and mercurochrome respectively. The hand was introduced into the fundus of the uterus, and numerous intramural fibroids were encountered. The placenta was definitely adherent and could not be removed without using more force than was justifiable. The patient was therefore prepared for laparotomy. A uterus which contained multiple fibroids was then removed supravaginally, leaving both tubes and ovaries.

Her postoperative course was complicated by a purulent vaginal discharge, beginning on the ninth

A series of selected case histories by members of the section will be published weekly.

Comments and questions by subscribers are solicited and will be discussed by members of the section.

day, although this had largely subsided by the time she left the hospital. Her temperature ranged from 99 to 101°F up until the sixteenth day, and there was a moderate amount of postoperative abdominal distention. She was discharged well on the twenty-first postoperative day.

The pathological examination revealed a postpartum uterus with placenta attached, the whole specimen measuring 21 by 10 by 13 cm. There were many fibroid tumors distorting the specimen, the principal ones being as follows: a subserous one, 9 by 6 by 6 cm, at the right cornu, a subserous one, 3 by 3 by 1 cm, at the fundus, and an intramural one, 5 by 5 by 4 cm, within the left lateral wall. There were six other similar tumors, all smaller, scattered throughout the rest of the organ. The placenta measured 14 by 13 by 11 cm and was firmly adherent to the uterine wall by its margins and in portions of its fundal attachment. The myometrium at the fundus measured 12 mm in thickness, although there was a cornual sacculation (diverticulum) whose wall was only 3 mm thick. Gentle to firm traction on the placenta did not dislodge it.

The microscopical examination of numerous sections revealed the picture of partial placenta accreta, complicated by acute inflammation. The spongy decidua basalis was absent, but occasional small areas of fibrosed, compact decidua remained at the placental site. In general, however, the placental villi were attached directly to the myometrium, which showed fibrosis and a variable degree of acute and chronic inflammation. The placental tissue, which was of normal, mature type, showed infiltration by acute inflammatory cells. The amniotic and chorionic membranes were especially involved in this process, probably associated with premature rupture of the membranes together with retention in the uterus fourteen hours post partum. The decidua vera likewise was deficient in its spongy, glandular layer, while the compact portion was deficient and fibrosed and showed variable degrees of acute and chronic inflammation.

*Comment.* This case is of extreme interest because of the fact that it occurred in a primipara, there being only one other such patient in the literature. Furthermore, the association of a placenta accreta with fibroid tumors and a diverticulum is very rare.

## DEATHS

DAVIS—FREDERICK D. DAVIS, M.D., of 233 Forest Park Avenue, Springfield, died December 31. He was in his fifty-fifth year.

Born in Blandford he graduated from the Westfield

schools, attended Amherst College for one year and received his degree from the University of Vermont College of Medicine in 1910. After serving his internship at the Backus Hospital in Norwich, Connecticut, he returned to Westfield and practiced medicine for five or six years. Dr. Davis went to Springfield in 1917 and specialized in neurology although he did some general practice. In 1929 he was made a member of the Mercy Hospital staff in Springfield.

Dr. Davis held memberships in the American Medical Association and the Massachusetts Medical Society.

His widow, his mother and two daughters survive him.

GREGG—DONALD GREGG, M.D., of Wellesley, died January 6. He was in his sixtieth year.

Born in Hartford, Connecticut, he moved as a child to Colorado Springs, Colorado, attending the public schools there. He prepared for college at Cutler Academy, graduated from Harvard College in 1902 and received his degree from Harvard Medical School in 1907. He served his internship during 1908-1909 at the Massachusetts General Hospital, after which he served four years as resident physician of the Philippine General Hospital at Manila, Philippine Islands. During one year there he was assistant professor of tropical medicine at the University of the Philippines.

Dr. Gregg returned to the United States in 1912 and began practicing in Wellesley. He became associated with Dr. Channing in the direction of the Channing Sanitarium at Wellesley, taking full charge at the time of Dr. Channing's death in 1922.

Among his affiliations were memberships in the American Medical Association, Massachusetts Medical Society, American College of Physicians, American Neurological Association, American Psychiatric Association, New England Society of Psychiatry, Association for Research in Nervous and Mental Disease and American Psychopathological Association.

His widow, three brothers and three sisters survive him.

MORGNER—RICHARD A. MORGNER, M.D., of Main Street, Fitchburg, died December 27. He was in his sixty sixth year.

After graduating from Clinton schools, he completed the course at Massachusetts College of Pharmacy, and then worked for two years as a druggist that he might attend medical school. He received his degree from Tufts College Medical School in 1902. After internship at the Chelsea Marine Hospital and the Lynn Hospital, in 1904 he went to Fitchburg, where his record of deliveries won for him an award from Tufts College Medical School.

He was a member of the American Medical Association and the Massachusetts Medical Society and was also on the senior surgical staff at the Burbank Hospital.

His widow and two children survive him.

## MISCELLANY

### 'YOUR HEALTH' BROADCASTS

The next series of "Your Health" broadcasts, sponsored by the American Medical Association and the National Broadcasting Company and heard over the Blue Network each Wednesday at 2:00 p. m., is entitled "Dodging Contagious Diseases." It consists of four broadcasts, the last three of which are as follows:

January 18 Scarlet Fever, Measles and Whooping Cough

Modern attitudes toward these diseases, prevention by community co-operation.

January 25 Smallpox and Diphtheria

Unnecessary diseases, preventable by immunization of infants

February 1 Preventing Epidemics

Reporting of cases, quarantine and other control measures

## NOTES

The following appointments to the staffs of the Harvard Medical School and the Harvard School of Public Health have been recently announced: Thomas R. C. Fraser, as research fellow in medicine, D.P.M. London '37, Alfredo Lanari, of Buenos Aires, as research fellow in physiology, M.D. Buenos Aires '34, Eric K. Cruickshank, of Aberdeen, Scotland, as research fellow in surgery, M.B., Ch.B. Aberdeen University '37, Maximilian G. Verlot, of Ghent, Belgium, as research fellow in surgery, M.D. Ghent '35, Adolph Meltzer, of New York City, as assistant in surgery, M.D. Cornell '34, Maurice H. Greenhill, as research fellow in psychiatry, M.D. University of Chicago '36, Nathan Gorin, of Boston, as assistant in child hygiene, M.D. Boston University School of Medicine '17.

The following fourth year students in the Harvard Medical School have been elected to membership in the Harvard chapter of Alpha Omega Alpha: John Adams, Eben Alexander, Lemuel Bowden, Jerome Frank, Charles Jennings, Ferdinand McAllister, Max Michael, Arthur Pier, Frederick Ross, John Wilson and Lucius Wing.

On January 1, Dr. Joseph B. Howland retired as superintendent of the Peter Bent Brigham Hospital, having served in that capacity since May 1, 1919—or nearly twenty years. He was succeeded by Dr. Norbert A. Wilhelm, a former assistant superintendent and, for the past two years, superintendent of the Butterworth Hospital, Grand Rapids, Michigan. Dr. Wilhelm graduated from St. Louis University School of Medicine in 1925.

## CORRESPONDENCE

### THE GREATER LAWRENCE MEDICAL ASSOCIATION

To the Editor: On December 14, the Greater Lawrence Medical Association held its second annual dinner. The guest speaker was Dr. Morris Fishbein, of Chicago, editor of the *Journal of the American Medical Association* who spoke on "The National Health Program and American Medicine."

His talk was broadcast over two radio networks and I thought it would be of interest to the fellows of the Society to know the favorable reaction of the public to his remarks. Many messages of praise have come back to us, most of which say that the doctors have a case after all. In view of the constant and almost continuous deluge of propaganda against the physicians of this country in the daily press and the weekly and monthly periodicals, it must be indeed refreshing at times to hear the doctors' side of the story. I am fairly convinced that the medical profession has lagged in this respect and it is, therefore, pleasing to see that through the efforts of the Massachusetts Medical Society a series of articles is now ap-

pearing in the *Boston Evening Transcript* This is good work, and too much of it cannot be done.

Yesterday the Greater Lawrence Medical Association invited Congressman Laurence J Connery at a special meeting, which was attended by a large number of physicians We presented our case to him in detail, and he apparently was very much impressed by our story He said that, although many physicians had asked him to vote against socialized medicine, no group in his congressional district had up to this time taken the trouble to discuss the subject with him He told us that he hoped that other organizations would get together with their congressmen, because he was sure that on their return to Washington the opposition would canvass every member of Congress

N F DE CESARE, M.D., *President*  
Greater Lawrence Medical Association

Lawrence Massachusetts

Medical students and physicians are cordially invited to attend

### MEDICAL CLINIC AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 p m on Thursday, January 19, in the amphitheater of the Peter Bent Brigham Hospital, Dr Samuel A Levine, assistant professor of medicine, Harvard Medical School and senior associate in medicine, Peter Bent Brigham Hospital, will give a medical clinic. Practitioners and medical students are cordially invited to attend.

### CENTRAL MASSACHUSETTS ALUMNI CLUB OF BOSTON UNIVERSITY SCHOOL OF MEDICINE

A symposium sponsored by the Central Massachusetts Alumni Club of Boston University School of Medicine will be held in the Worcester State Hospital Chapel (Administrative Building), Belmont Street, Worcester, on Wednesday, January 18, at 8 00 p m.

The symposium The Recent Epidemic, in Human Beings, of Encephalomyelitis in Massachusetts A clinical, pathological and immunological study will be given by Dr Edward C Smith, Dr Charles F Branch and Dr LeRoy D Fothergill

Physicians medical students and nurses are cordially invited to attend

### NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The next meeting of the New England Society of Physical Medicine will be held at the Hotel Kenmore, Boston, on Wednesday evening, January 18 The Council will meet at 6 00, there will be an informal dinner at 6 30 in the Empire Room

#### PROGRAM

Organic Arterial Disease (with colored slides) Dr Edward A Edwards Discussion Dr Laurence B Ellis  
All members of the medical profession are cordially invited to attend.

WILLIAM D McFEE, M.D., *Secretary*

### NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held in the Mallory Amphitheater, Boston City Hospital, Monday, January 23, at 8 15 p m.

#### PROGRAM

Clinicopathological Correlations Dr Soma Weiss  
Study of the Presystolic Murmur of Mitral Stenosis and the Factors Influencing the Intensity of the First Heart Sound Dr Eugene A. Stead, Jr  
The Effect of Anemia on the Heart, with Particular Reference to Electrocardiographic Changes Dr Laurence B Ellis  
Influence of the Peripheral Circulation in the Upper Extremities on the Circulation Time as Measured by the Sodium Cyanide Method Dr Paul Kunkel  
Blood Flow and Vasomotor Reactions of the Hand, Forearm, Foot and Calf in Response to Physical and Chemical Stimuli Dr Eugene A Stead, Jr  
Thrombosis of the Ductus Arteriosus with Embolic Manifestations Dr Blair V Jager  
Gummatous Aortitis Dr William H. Gordon.

EDWARD F BLAND, M.D., *Secretary*

### NEW ENGLAND WOMEN'S MEDICAL SOCIETY

The annual meeting of the New England Women's Medical Society will be held at the Myles Standish Hotel, Thursday, January 19

Hon. Paul Dever, attorney general of Massachusetts, will be the speaker

A business meeting will be held promptly at 6 30 p m. Dinner will be served at 7 15

MARY I TOMPKINS, M.D., *Secretary*

### MASSACHUSETTS MEMORIAL HOSPITALS

There will be a luncheon meeting of the surgical section in the Aid Association Room, Talbot Memorial, 82 East Concord Street, on Tuesday, January 17, at 12 o'clock noon.

Surgical deaths during the month of November will be discussed

MILO C GREEN, M.D., *Secretary*

### CARNEY HOSPITAL

The monthly clinical meeting and luncheon of the Carney Hospital will be held in Andrew Carney Assembly Room on Monday, January 16, at 11 30 a m

#### PROGRAM

Case reports  
Anesthesia in Abdominal Surgery Dr H. Bruce MacEwen Discussion Drs Joseph Kennedy, H L. Brayton and John S Kelley

Physicians and medical students are cordially invited to attend

ROY J HEFFERNAN, M.D., *Secretary*

## BOSTON LYING IN HOSPITAL

The next meeting of the Journal Club will be held on Wednesday evening, January 18, at 8 30

Dr Herbert Thoms, of the Yale University School of Medicine, will present a paper "The Obstetric Pelvis" Classification of the abnormal types, roentgenometry and its relation to labor will be illustrated by lantern slides and moving pictures

Physicians and students are invited to attend

DUNCAN E REID, M D, *Secretary*

## MASSACHUSETTS ITALIAN MEDICAL SOCIETY

The next meeting of the Massachusetts Italian Medical Society will be held on Friday evening, January 20, at the Hotel Kenmore, Boston, at 9 00

## PROGRAM

Business meeting

Relations of the Dental Profession to the Medical Field  
V J Pollina, DMD, president of the Italian American Dental Society of New England

Functions of the Board of Registration in Medicine D A Costa, MD

Members of the medical and dental professions are cordially invited to attend.

CARL F MARALDI, M D, *Secretary*

## NEW ENGLAND PATHOLOGICAL SOCIETY

The next meeting of the New England Pathological Society will be held at the Mallory Institute of Pathology, Boston City Hospital, on Thursday evening, January 19, at 8 00

Dr Paul A Younge will speak on "Pre-invasive Carcinoma of Cervix Uteri"

Physicians and medical students are cordially invited to attend

GRANVILLE A BENNETT, M D, *Secretary*

## SOCIETY MEETINGS AND CONFERENCES

## CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, JANUARY 16

## MONDAY JANUARY 16

- \*11 30 a m Carney Hospital Monthly clinical meeting and luncheon  
Andrew Carney Assembly Room

## TUESDAY JANUARY 17

- 9 10 a m Joseph H Pratt Diagnostic Hospital Clinicopathological conference Dr Harold Wood Discussion by Dr Chester Keefer
- \*10 a m 12 30 p m Tumor clinic Boston Dispensary
- 12 m Massachusetts Memorial Hospitals Luncheon meeting of the surgical section Aid Association Room Talbot Memorial 82 East Concord Street Boston
- \*12 m South End Medical Club Headquarters of the Boston Tuberculosis Association 554 Columbus Avenue Boston

## WEDNESDAY JANUARY 18

- \*9 10 a m Joseph H Pratt Diagnostic Hospital Hospital case presentation Dr S J Thannhauser
- \*12 m Clinicopathological conference Children's Hospital amphitheater
- \*6 p m New England Society of Physical Medicine Hotel Kenmore
- \*8 30 p m Boston Lying in Hospital Journal Club meeting

## THURSDAY JANUARY 19

- 8 30-9 30 a m Exchange visit, Surgical and Orthopedic Staffs of the Peter Bent Brigham and Children's hospitals held this week at the Peter Bent Brigham Hospital
- \*9 10 a m Joseph H Pratt Diagnostic Hospital The Management of Lacerations of the Perineum with Special Reference to Complete Lacerations Dr L E Phancuf
- \*3 30 p m Medical clinic at the Peter Bent Brigham Hospital
- 6 30 p m New England Women's Medical Society Myles Standish Hotel Boston
- \*8 p m New England Pathological Society Boston City Hospital Mallory Institute of Pathology

## FRIDAY JANUARY 20

- 9 10 a m Joseph H Pratt Diagnostic Hospital Varieties of Thrombophlebitis and Their Relation to Embolism Methods of prevention and treatment Dr John Homans
- \*10 a m 12 30 p m Tumor clinic Boston Dispensary
- 12 m Clinical meeting of the Children's Medical Service Massachusetts General Hospital Ether Dome
- \*9 p m Massachusetts Italian Medical Society Hotel Kenmore Boston

## SATURDAY JANUARY 21

- \*9 10 a m Joseph H Pratt Diagnostic Hospital Hospital case presentation Dr S J Thannhauser
- \*10 a m 12 m Staff rounds of the Peter Bent Brigham Hospital Conducted by Dr Henry A Christian

## SUNDAY JANUARY 22

- 4 p m Illustrated public health lecture Fankner Hospital auditorium Reasons for High Standards in Medical Education and Practice, Dr Alexander S Begg
- 4 p m Free public lecture Harvard Medical School amphitheater of Building D Cancer Dr Tracy B Mallory

\*Open to the medical profession

## THE TREATMENT OF GONORRHEAL AND RHEUMATOID ARTHRITIS WITH SULFANILAMIDE\*

HOWARD C. COGGESHALL, M.D.,† AND WALTER BAUER, M.D.‡

BOSTON

THE reports to date<sup>1-3</sup> indicate that sulfanilamide is as effective as specific antiserum in the treatment of meningococcal infections. These results and the close biological relations between the meningococcus and the gonococcus have suggested to various workers<sup>4-9</sup> that sulfanilamide might have a similar effect on gonococcal infections. Because of the difficulties encountered in producing gonococcal infections in animals, experimental studies similar to those employed in determining the chemotherapeutic value of sulfanilamide in hemolytic streptococcal,<sup>10-15</sup> meningococcal<sup>16</sup> and pneumococcal<sup>17-18</sup> infections have not been attempted. Therefore establishment of the efficacy of sulfanilamide therapy against gonococcal infections must be based on clinical results.

The results obtained by certain investigators<sup>3, 4, 8, 19-21</sup> suggest that sulfanilamide is effective in treating uncomplicated gonococcal infections. The use of this drug in the treatment of gonorrheal arthritis, however, has been limited.<sup>3, 5, 6, 9</sup> Heretofore we have agreed with other workers<sup>22-26</sup> that artificially induced fever represents the nearest approach to a specific form of therapy for gonorrheal arthritis. We observed that fever therapy was satisfactory in arresting the arthritis in 80 patients, but noted that many of the associated genitourinary infections persisted. Because of the hazards of fever therapy and our inability to cure more regularly the genitourinary focus, we were led to investigate the effect of sulfanilamide§ on gonorrheal arthritis. Sim-

ilar studies were made on patients suffering from rheumatoid arthritis in order to compare the results in an arthritis of unknown origin (rheumatoid arthritis) with those in one of known origin (gonorrheal arthritis). In order to be assured of the greatest possible number of cures, sulfanilamide was administered in most cases in large daily doses for several weeks. The results obtained and the various toxic manifestations—their significance and possible control—observed during and following this form of administration will be presented.

### METHODS EMPLOYED

No case was included as proved gonorrheal arthritis unless the following criteria were satisfied: a history of gonorrheal infection, a history of joint disease consistent with gonorrheal arthritis, the isolation of gonococci from the genitourinary focus or synovial fluid. Probable gonorrheal arthritis was diagnosed when the first two requirements were met and the gonococcal complement-fixation test was positive. To date we have treated 18 cases of gonorrheal arthritis, of which 14 were proved and 4 probable.

One (Case 22) of the 10 cases of rheumatoid arthritis treated with sulfanilamide had an associated gonorrheal genitourinary infection. This patient gave a history of a progressive symmetrical arthritis antedating the onset of the gonococcal infection. Two cases (23 and 24) had a history of a previous urethritis. Both patients had chronic prostatitis and positive gonococcal complement-fixation tests. Gonococci were never isolated in either case. The gonococcal infection antedated the rheumatoid arthritis by two and seventeen years respectively.

Two cases of uncomplicated gonorrhea and 1 with an associated ischial bursitis have been included. They demonstrate the effect of sulfanilamide therapy on the genitourinary focus, as well as illustrate certain toxic manifestations which may be encountered.

This is publication No. 26 of the Robert W. Lovett Memorial for the Study of Crippling Disease, Harvard Medical School.

From the Medical Clinic of the Massachusetts General Hospital, the Department of Medicine, Harvard Medical School, and the Massachusetts Department of Public Health.

The expenses of this investigation have been defrayed in part by grants from the John and Mary R. Markle Foundation and the Commonwealth Fund.

Presented at the Association of American Physicians, May 5, 1938, and the American Rheumatism Association, June 13, 1938, and in part at the annual meeting of the New Hampshire Medical Society, Manchester, May 18, 1938.

\*Research fellow in medicine, Harvard Medical School; assistant in medicine, Massachusetts General Hospital.

†Associate professor and tutor in medicine, Harvard Medical School; physician, Massachusetts General Hospital.

§Much of the sulfanilamide employed in this study was furnished through the courtesy of the Department of Medical Research, Winthrop Chemical Company, New York City.

Roentgenograms were taken of all involved joints at the time of entry and prior to discharge, and oftener if indicated. Complete blood studies and urinalyses were made at frequent intervals during and following the administration of sulfanilamide. Serum nonprotein nitrogen determinations were usually made prior to and following treatment. Urine-concentration and divided phenolsulfonephthalein urine-excretion tests<sup>27</sup> were made before and after sulfanilamide therapy in a few cases. They were always carried out if there was any reason to suspect the existence of renal impairment. Bromsulfalein liver-function tests were carried out on a few patients prior to and following treatment. Serum-chloride,<sup>28</sup> carbon-dioxide combining power<sup>29</sup> and bilirubin determinations<sup>30</sup> were usually made at biweekly intervals. The sedimentation rates were determined frequently<sup>31</sup>. Free sulfanilamide determinations<sup>32, 33</sup> were made on serum or whole blood at frequent intervals in most cases.

#### ADMINISTRATION OF SULFANILAMIDE

All patients were hospitalized. The sulfanilamide was administered by mouth except in Case 1, in which an initial dose of 90 cc of 25 per cent Protosil solution was given intramuscularly. Large doses were employed in all cases unless the drug caused marked gastric or toxic symptoms. In that event it was reduced to two thirds or half the original dose. The dose was calculated in the following manner:  $\frac{3}{4}$  gr per pound of body weight or 1 gm per 20 pounds of body weight, provided the total dose did not exceed 120 gr or 8 gm. In some cases half the total calculated dose was administered initially and again in four hours. Then, in order to maintain a constant blood-sulfanilamide level, one sixth of the total calculated dose was given every four hours day and night. In most cases one sixth of the total calculated twenty-four hour amount was given every four hours, beginning with the initial dose. The latter method did not enable us to maintain so high a blood-sulfanilamide level as is at times necessary. Most patients received such doses of the drug for two weeks or longer. In some cases half or one third the calculated daily dose was continued for another two weeks. In Case 2 the drug was administered in full doses for only one week and then discontinued. An equal dose of sodium bicarbonate was administered with each dose of sulfanilamide except in Cases 3, 15, 18, 21, 30 and 31. This practice seemed to lessen the gastric symptoms, and theoretically speaking is supposed to aid in counteracting the accompanying so-called acidosis.<sup>34</sup>

#### CLINICAL RESULTS

##### *Proved Gonorrheal Arthritis with Infected Synovial Fluids*

Of the 14 cases having proved gonorrheal arthritis, the most significant results were obtained in Cases 1, 2 and 3. These presented extremely painful joints from which gonococci were isolated. This is the type of gonorrheal arthritis which if allowed to go untreated is very liable to end with considerable joint destruction and some permanent loss of function. In order to prove that sulfanilamide is a specific chemotherapeutic agent for gonorrheal arthritis, it must be demonstrated that this form of therapy arrests more promptly and effects a larger percentage of cures in severe gonorrheal arthritis with infected synovial fluids than do other forms of therapy. Conclusions based on the results obtained in the treatment of milder cases of gonorrheal arthritis are very apt to be erroneous, because the end results are very satisfactory in a large percentage of this group when nothing more than bed rest and good supportive treatment are employed. Because the results in Cases 1, 2 and 3 are so striking, the clinical records are presented in some detail.

*Case 1* E. S., a 24 year-old, married Italian woman, entered the hospital with a diagnosis of rheumatic fever. Four weeks previously, following coitus, she had developed leukorrhea and dysuria. Four days later she had a severe shaking chill followed by a temperature of 104°F., headache and severe pain in the jaws, neck and lower back. The left knee became acutely swollen and painful 10 days prior to entry. (This knee had been injured 1 month before, but was considered normal just prior to the onset of the arthritis.) The patient had had acute rheumatic fever at the age of 9 without cardiac complications.

Physical examination was normal except for an extremely painful, red, swollen, flexed left knee joint containing an increased amount of synovial fluid, acute endocervicitis and profuse vaginal discharge. The knee was so painful that immobilization with a cast, opiates and analgesics were required. Gonococci were demonstrable in the aspirated synovial fluid and the cervical smears. The temperature for 3 days prior to treatment was 100 to 102°F. X-ray examination of the left knee was negative except for an effusion and swelling of the soft tissue.

Three days after entry the patient received 90 cc. of 25 per cent Protosil solution intramuscularly. This was followed by 1 gm. of sulfanilamide plus the same amount of sodium bicarbonate every 4 hours day and night for 11 days. Twenty-four hours after the institution of sulfanilamide therapy, opiates and analgesics were no longer required. Forty-eight hours later the cast was removed. The knee then had 30 degrees of voluntary painless motion, 2 days later this had increased to 90 degrees. Within 2 weeks the knee was painless, motions were normal and weight-bearing was possible. There remained slight swelling in the region of the infrapatellar fat pad. As can be seen from Table 1, the synovial fluid became sterile on the 2nd day of therapy and the synovial fluid leukocyte count fell from an initial level of 41,000 (98 per cent polymorphonuclears) to 1000 (6 per cent polymorphonuclears).

in 7 days. All pelvic smears obtained after the 1st day of treatment were negative for gonococci, and the fixation test never became positive (Table 2). The serum carbon dioxide combining power never fell below 57.4 vol per cent. The initial sedimentation rate was 169 mm per minute, 3, 5 and 12 weeks later it was 0.79, 0.43 and 0.29 mm respectively. The hematologic changes which occurred are presented in Table 3.

had developed acute pain, heat, redness and swelling of the right knee. Unl entry she had received no medication other than morphine to control the intense pain. There was no history of other joint involvement, chills or fever. Her husband, who was being treated for gonorrhea, also developed acute pain and swelling in his feet 4 days after the onset of her arthritis.

Physical examination was essentially normal except for

Cyanosis was present throughout the period of therapy. The temperature which had been 102 to 105°F from the 4th to the 11th day disappeared 24 hours after discontinuance of the drug. No other toxic symptoms were noted.

**Summary.** A patient with proved acute gonorrheal arthritis and endocervicitis responded promptly to large doses of sulfanilamide. She made a complete recovery

an intensely painful, red, swollen effused right knee, edema of the right lower leg, profuse vaginal discharge, endocervicitis and pallor of the mucous membranes and skin. The knee was held in 5-degree flexion. The overlying skin was hot. Because of the intense pain the patient resisted any attempt to move the joint. Gonococci were demonstrated in the smears and cultures of the

after 11 days of such therapy. During a 46-week follow-up period, she has remained well, all clinical examinations and laboratory tests being normal.

**Case 2.** A S., a 39-year-old, married woman, entered the hospital with acute gonorrheal arthritis and endocervicitis. Five months previously she had noticed a profuse leukorrhea, frequency of urination, dysuria and nocturia. Three weeks prior to entry, after scrubbing the floor she

synovial fluid none were ever found in repeated pelvic smears. The highest temperature recorded prior to treatment was 99.5°F. Roentgenograms showed considerable soft tissue swelling and a joint effusion. There was moderate flecky decalcification of the femoral and tibial condyles. The medial surfaces of both the femur and the tibia showed areas of destruction.

Sulfanilamide therapy was begun on the day of entry.

She received 7 gm a day for 7 days. This dosage maintained a blood sulfanilamide level of 94 mg per cent. Forty-eight hours after institution of sulfanilamide therapy there was marked reduction of pain and swelling. Much of the redness and throbbing pain had disappeared. Three days after starting therapy there was 10 degrees of painless motion. One week after treatment the knee could be flexed 45 degrees and extended to 180 degrees. Ten days later 90 degrees of flexion was possible without pain. At this time a moderate degree of soft-tissue swelling persisted, particularly in the region of the quadriceps pouch. At the time of the 7-week follow-up, walking was painless, extension 180 degrees and flexion 90 degrees.

No synovial fluid was obtained on the 3rd day, and that aspirated on the 4th day was sterile. The blood complement fixation test on the day of entry was negative and never became positive, whereas the synovial fluid obtained on the day of entry was positive. The initial sedimentation rate was 175 mm per minute, 3, 5, 7, 11 and 13 days later it was 136, 136, 043, 025 and 018 mm respectively. The hematologic variations noted were a reticulocytosis of 22 per cent, a macrocytic anemia and a marked leukocytosis (Table 3). The serum bilirubin remained normal. The serum carbon-dioxide combining power fell to 48.3 vol per cent. The lowest serum chloride observed was 97 milliequivalents.

Roentgenograms taken 10 days after cessation of therapy revealed no effusion and only slight soft tissue swelling. The previously described changes were still present but seemingly less marked. Four weeks later the flecky decalcification and a small area of destruction in the tibial condyle were still present. Four weeks later the x-ray report read: 'The joint surfaces visible are well restored. Subchondral, flecky decalcification in the subchondral regions of all the bones forming the knee joint is still present. No soft tissue swelling is demonstrable.'

Cyanosis and mild vertigo were present during the period of treatment. No other toxic symptoms were noted.

**Summary** An acute case of proved gonorrheal arthritis of 21 days duration was promptly arrested by the institution of sulfanilamide therapy, as shown by marked subsidence of the joint signs and symptoms and sterilization of the synovial fluid.

**Case 3** K. W., an 18-year-old, single Negress, entered the hospital with a diagnosis of acute rheumatic fever. Ten days prior to entry she had developed an acute upper respiratory infection with associated sweating, malaise and generalized aching. One day later the right wrist and both elbows became hot, swollen and tender. There was no previous history of genitourinary or arthritic symptoms.

Physical examination was normal except for exquisitely painful and swollen right wrist and elbows, acute endocervicitis and a profuse vaginal discharge. The left elbow was so painful as to forbid motion. Gonococci were found in the synovial fluid from the left elbow and in the cervical smears. During the 8 days preceding sulfanilamide therapy analgesics and opiates were necessary to control pain. During this time the temperature fluctuated between 99.5 and 103 F. X-ray examination showed marked soft-tissue swelling of the involved joints and atrophy of the bones of both elbows.

Eight days after entry sulfanilamide therapy was begun, the patient receiving 6.6 gm per day for 12 days. Forty-eight hours after the institution of therapy analgesics and opiates were no longer required, the motions present were painless and marked reduction of the swelling had occurred. From this time on improvement was rapid.

Three days later massage and passive motions were begun. At this time the left elbow had approximately 120 degrees of motion. Nine days after cessation of treatment the joints were symptom free and motions were normal except for the left elbow, which lacked 5 degrees of full extension. Five pelvic smears after the 1st day of treatment were negative. The blood complement fixation test, which was doubtful on entry, never became positive. The initial sedimentation rate was 212 mm per minute, 1, 3 and 4 weeks later it was 1.95, 1.84 and 1.07 mm respectively. Sulfanilamide therapy apparently caused a marked macrocytic anemia, a reticulocytosis of 20 per cent and a leukopenia of 1800 (Table 3). Icterus, bilirubinemia and urobilinogenuria were never demonstrable.

Repeated x-ray examinations revealed no other changes than those noted. The effusion and soft tissue swelling disappeared 3 weeks after the institution of therapy.

The patient was slightly drowsy and occasionally euphoric during the period of treatment. No other toxic symptoms were observed.

**Summary** A patient with proved acute gonorrheal arthritis and endocervicitis made an excellent recovery after 12 days on large doses of sulfanilamide. At the time of discharge she had slight stiffness of the left elbow on full extension.

These 3 cases of proved acute gonorrheal arthritis with infected synovial fluids were promptly arrested following the administration of large doses of sulfanilamide. Cases 1 and 3 illustrate the desirability of instituting such therapy as early as possible if irreparable joint damage is to be prevented and normal joint function preserved. In Case 2 the response to therapy was equally as prompt as in Cases 1 and 3, as shown by the marked clinical improvement and sterilization of the infected synovial fluid. Repeated roentgenograms demonstrated that destruction of the joint was arrested and recalcification of the subchondral bone made possible. However, sufficient intra-articular changes had taken place prior to the institution of therapy to prevent restoration of normal joint function. From the results in these cases it is apparent that with large doses of sulfanilamide marked clinical improvement can occur as early as forty-eight to seventy-two hours following their institution. Corroborative laboratory evidence of this improvement is obtained from repeated synovial-fluid analyses. Such analyses reveal that the infected fluid may become sterile within forty-eight hours (Table 1). With the sterilization of the synovial fluid the cytologic abnormalities may be restored to practically normal values within seven days. The genitourinary foci seemed to respond equally as well to sulfanilamide, in that no gonococci were isolated after forty-eight hours of therapy. The blood complement-fixation test never became positive in these cases. These results suggest that if large doses of sulfanilamide are to be therapeutically effective in a given case, improvement may be expected as early as forty-

\*See Table 3 for detailed data concerning anemia

eight to seventy-two hours after institution of treatment

*Proved Gonorrheal Arthritis with Synovial Fluids Containing No Demonstrable Gonococci*

Six (Cases 4, 5, 6, 7, 8, and 11) of the remaining 11 patients with proved gonorrheal arthritis obtained marked relief of their joint symptoms two to three days after the institution of sulfanilamide therapy (Table 4). Of these 6 patients, 4 (Cases 4, 5, 8 and 11) made uneventful recoveries with complete restoration of joint function. Two patients (Cases 6 and 7) failed to regain normal joint function. Their joints were 90 to 95 per cent normal at the time of the last follow-up. In these 2 cases there was roentgenologic evidence of joint destruction prior to treatment

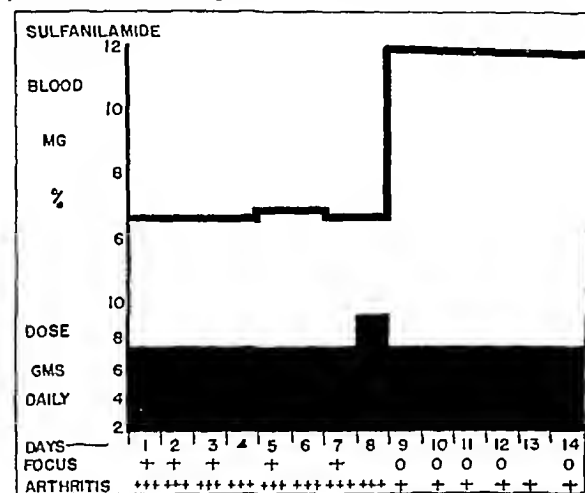

Chart 1 Case 9

*This chart shows that the gonococcal prostatitis and arthritis failed to respond when the blood sulfanilamide level was kept at 6.4 mg per cent. Twenty-four hours after reaching a level of 11.8 mg per cent the joint pain diminished and gonococci disappeared from the prostatic smears and cultures.*

Two patients (Cases 9 and 10) in this group with arthritis of short duration and no roentgenologic evidence of joint destruction failed to show obvious improvement in their joint symptoms until the sulfanilamide dosage had been increased sufficiently to raise the blood-level above 10 mg per cent. They both regained normal joint function. In Case 9 the genitourinary focus did not become negative until the blood sulfanilamide reached 11 mg per cent (Chart 1).

Two other patients (Cases 12 and 13) with arthritis of four and seven days' duration and without roentgenologic evidence of joint destruction were first treated with large doses for thirteen and twenty-two days respectively. In neither case was the improvement in the arthritis any more

rapid than might be expected with good conservative treatment and bed rest. The blood sulfanilamide level never rose above 6.8 mg per cent in either patient. Although the arthritis was seemingly uninfluenced by the drug, gonococci could not be isolated from the genitourinary focus after the second day. The fixation tests became negative forty-three and forty-four days respectively after cessation of therapy. From Table 5 it is seen that the cytologic abnormalities in the synovial fluid were uninfluenced by the drug, corroborating the clinical impression that no improvement in the arthritis had occurred. These 2 patients had received small doses (10 to 15 gr three or four times a day) of sulfanilamide prior to entry, without benefit. The drug was readministered in both these cases (Table 4, Cases 12 and 13) in order that we might note the effect of therapy with a blood level of 10 mg per cent or higher. Seventy-two hours after the blood-sulfanilamide level had reached 10 mg per cent the joint pains had subsided. One week later the knee effusions had completely disappeared.

One patient (Case 14) entered the hospital during the fifth month of his arthritis. He had an associated keratoderma blennorrhagicum, with the characteristic skin and nail lesions. His improvement following sulfanilamide administration (large doses for 7 days on one occasion and 14 days on another) was very slow but progressive. The skin and nail lesions seemingly cleared more rapidly than they do in untreated cases. Despite the fact that he received sufficient sulfanilamide to maintain a blood-sulfanilamide level from 11.7 to 17.4 mg per cent, gonococci were still present in the prostatic smears after the two courses of therapy.

This patient had also received small doses of sulfanilamide prior to the onset of his arthritis. At the time of discharge five weeks after the second course of sulfanilamide therapy, the skin and nails were normal but there was still some residual morning aching and stiffness. The deformity of the left first metacarpophalangeal and the right first metacarpophalangeal joints persisted. Two months later the patient returned to his work as a carpenter and was normal except for the last mentioned residual joint deformities. Because of failure to cure the genitourinary focus, he was given 10 per cent Neosilvol urethral instillations three times a day for ten successive days prior to discharge. During the follow-up period he received prostatic massages two or three times a week. Three months following discharge gonococci were no longer demonstrable in the prostatic smears. Three subsequent prostatic smears and cultures obtained after this were likewise negative for gonococci.

Thus it will be seen that in this group the results were equally as satisfactory in Cases 4, 5, 6, 7, 8 and 11 as they were in the patients with infected synovial fluids. The results in Cases 9, 10, 11 and 12 suggest that blood-sulfanilamide levels of 10 mg per cent or higher are at times necessary to bring about clinical cures. It is interesting that the patients (Cases 12, 13 and 14) who did not respond so favorably as the others in this group had received small doses of the drug—and during the day only—prior to hospital entry. This might be interpreted to mean that sulfanilamide administered in doses too small to effect a cure may increase the resistance of the

tion prior to treatment and only 5 per cent normal motion was regained. In the 2 remaining patients (Cases 17 and 18) with probable gonorrheal arthritis immediate improvement forty-eight to seventy-two hours after the institution of therapy was not observed. In Case 17, although the arthritis had been present for seventy-five days before receiving the drug, the roentgenograms revealed no evidence of joint destruction. This patient made a complete recovery except for slight residual aching. In Case 18 the patient showed evidence of narrowing and destruction of the left elbow joint at the time of entrance into the hospital, fifty-four days after onset of her disease.

Table 5 *Synovial Fluid Findings in Two Cases of Gonorrheal Arthritis Which Failed to Respond to the First Course of Sulfanilamide Therapy*

CASE NO (AGE AND SEX)	DAILY DOSE OF SULFANILAMIDE	TIME IN RELATION TO FIRST DAY OF THERAPY	SYNOVIAL FLUID FINDINGS*

		36th	40	10,200	78	Negative	

\*Synovial fluid sugars in both instances were normal throughout the period of observation.

organism. The clinical results observed in these last 3 cases suggest the possibility that the organisms in the joint and the genitourinary focus were not equally susceptible to the drug. However, we have no proof for such statements.

The results obtained in these 11 cases show that proved gonorrheal arthritis without demonstrable gonococci in the synovial fluids, if treated with large doses of sulfanilamide, may respond equally as well and as promptly as do cases having infected synovial fluids. They also demonstrate the necessity of adequate treatment being instituted early if the largest potential percentage of cures without residual joint changes is to be obtained.

#### *Probable Gonorrheal Arthritis*

Two of the 4 patients with probable gonorrheal arthritis (Cases 15 and 16) responded as promptly to sulfanilamide therapy as did any one of the patients in the two previous groups. In Case 15 there was complete recovery. Case 16 showed roentgenologic evidence of joint destruc-

tion. She improved gradually. At the time of the last follow-up the left elbow joint had 90 per cent of normal motion. At the onset of her arthritis this patient had received 5 gr of sulfanilamide four times a day for twenty-one days.

The results in this group again suggest the importance of early treatment with large doses in order to obtain the highest percentage of clinical cures.

#### *Rheumatoid Arthritis*

In an attempt to establish that the clinical cures observed in this group of patients with gonorrheal arthritis represented a specific effect of sulfanilamide therapy on the gonococcus, it was deemed necessary to obtain similar data from cases with some other type of arthritis. Patients with rheumatoid arthritis were chosen because this disease is one of unknown etiology and has many features suggesting an infectious origin. It was thought that the results obtained in this group would also enable us to determine whether or not rheumatoid arthritis is due to an infectious agent.

which is similarly affected when exposed to large doses of sulfanilamide

A total of 10 patients with rheumatoid arthritis were treated. Nine of them received large doses of sulfanilamide for periods varying from eight to twenty-seven days (Table 6). In Case 19 the patient became so apprehensive because of mild gastric symptoms and vertigo that the dose was reduced on the third and fourth days and was discontinued four days later. Except in Case 20 there occurred no improvement in joint symptoms and no appreciable drop in sedimentation rates during the time sulfanilamide was given or during the subsequent follow-up periods. In fact, 2 of the patients (Cases 21 and 22) developed joint effusions during the period of therapy. In Case 20 the patient, who had typical mild rheumatoid arthritis of seven and a half months' duration, experienced almost complete relief subsequent to the development of a continuous fever (102 to 103°F for eight days). The fever disappeared promptly following the discontinuance of the drug. In this case the sedimentation rate returned to normal ten days after treatment. It was still normal nine weeks later. At this time the patient complained of joint symptoms, which required acetylsalicylic acid for control. Judging from our past experience with fever therapy in patients with rheumatoid arthritis,<sup>35</sup> it seems fair to ascribe the improvement noted in this particular case to the eight days of continuous fever caused by the drug. Mild rheumatoid arthritis of short duration is the type which responds most favorably to fever therapy.

In Case 22 the gonorrheal urethritis and prostatitis of six months' duration were clinically cured after the third day of therapy, but the arthritis of four years' duration was unaffected. In Case 21, with a chronic prostatitis of ten years' duration and a positive complement-fixation test, the patient noted no improvement in his arthritis (eight years' duration) during or following sulfanilamide therapy. The prostatitis improved and the complement-fixation test became negative. Case 24, with mild rheumatoid arthritis of four months' duration, showed a chronic prostatitis (seventeen years' duration) and a positive complement-fixation test. Sulfanilamide therapy resulted in marked improvement in the prostatitis and the complement-fixation test became negative. The arthritis, however, was uninfluenced.

From the clinical results obtained in these 10 cases of rheumatoid arthritis, it seems fair to conclude that sulfanilamide therapy does not exert any specific effect on the agent causing rheumatoid arthritis, nor does it influence the course of the disease. Failure to affect the arthritis in 3

of these patients, despite the fact that the gonococcal foci improved, is further evidence that sulfanilamide has a specific effect on the gonococcus and none on the agent responsible for rheumatoid arthritis.

#### EFFECT ON THE SEDIMENTATION RATE

The sedimentation rate was tested at frequent intervals in order to determine whether it fell as the gonorrheal arthritis improved. From Table 4 and Chart 2 it will be seen that such a relation

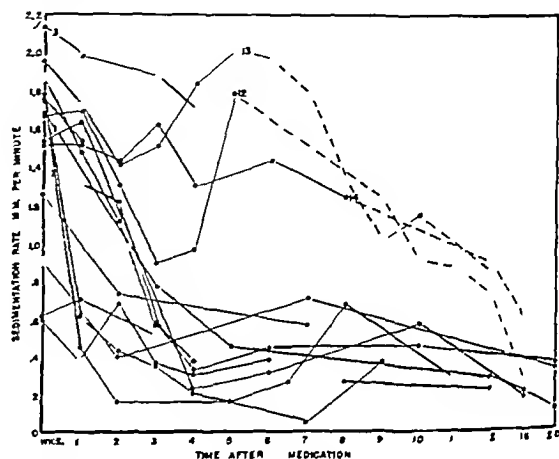

Chart 2 Corrected Sedimentation Rates in Cases of Gonorrheal Arthritis

Here one notes that there occurred a rapid decrease in the corrected sedimentation rates of the bloods of most of the patients with gonorrheal arthritis following the institution of sulfanilamide therapy. Cases 1, 2 and 3 had infected synovial fluids. Cases 12, 13 and 14 did not respond to the first course of sulfanilamide therapy (solid line) but did respond when it was administered a second time (broken line). The normal corrected sedimentation rate varies from 0.08 to 0.35 mm per minute.

was found with great regularity. It should be noted that the most rapid decrease in sedimentation rate took place in the patients showing striking improvement and that in the cases which improved slowly a correspondingly slow return of the sedimentation rate to normal was observed. The sedimentation rates remained fairly constant in 3 patients (Cases 12, 13 and 14) during the time the arthritis remained stationary or improved slowly. In Cases 2, 5, 6, 11, 15, 16 and 17 it returned to normal in four weeks. Such rapid falls in sedimentation rates are rarely observed in gonorrheal arthritis with other forms of treatment except in mild cases. With other forms of therapy it frequently remains elevated for three to twelve months. From Table 6 and Chart 3 one notes that the sedimentation rates remained unchanged or were only slightly altered in the 10 cases of rheuma-

Table 6 Results Observed in Patients with Rheumatoid Arthritis During and Following Sulfanilamide Therapy

CASE NO (AGE AND SEX)	DURATION OF JOINT SYMPTOMS	SULFANILAMIDE DAILY DOSE	BLOOD LEVEL	TIME IN RELATION TO FIRST DAY OF THERAPY	TOXIC MANIFESTATIONS	SIDE EFFECTS	LABORATORY DATA			CAMP SUMMARY AND REMARKS
							LOWE'S PLASMA CARBON DIOXIDE CONCENTRATION	SEDIMENTATION RATE	SEDIMENTATION RATE	
	yr	gm	mg %	day		mm per min	vol %	mm per min	mm per min	
19 (48 M)	27	8 (3 days) 6 (1 day) 1 (5 days)		Before After 96th	Cyanosis vertigo nausea	Not done 1 23	Not done	Not done	Not done	Mild atypical progressive rheumatoid arthritis and chronic nonspecific prostaticitis. No improvement of joint symptoms during therapy. Arthritis unchanged at the end of a 3 month follow up period.
20 (40 M)	2/3	6 (11 days)		Before After 7th 14th 21st 57th	Cyanosis fever euphoria	0.58 0.88 0.66 0.18 0.18	Not done	Not done	Not done	Mild typical rheumatoid arthritis (acute onset). Symmetrical joint involvement. During the first 3 days of therapy joint pain increased. Developed sustained temperature (102.103°F) on fourth day which continued until drug was omitted. Joint pain swelling and stiffness improved sixteen weeks later. Improvement maintained except for minimal stiffness and aching.
21 (32 M)	8	6 (12 days) 2 (12 days)	13.0 + 5.0 +	Before After 14th 21st 30th 56th 84th	Cyanosis	1.62 1.67 1.34 1.35 1.42 1.42 1.26	55.3	100	102	Moderately severe progressive rheumatoid arthritis (typical). Spondylitis with symmetrical joint involvement. No improvement with sulfanilamide therapy. Effusion of the left knee developed during the 3rd week of therapy. Arthritis unchanged during 6-month follow up period.
22 (24 M)	4	6 (14 days) 2 (14 days)	8.0 + 5.0 +	Before After 19th 21st 30th 44th	Cyanosis vertigo	1.43 1.41 1.62 1.28 1.44	52.5	99	102	Mild slowly progressive rheumatoid arthritis (typical). Six months prior to entry contracted acute gonorrhea. No improvement of joint symptoms during sulfanilamide therapy. Urethral discharge disappeared 2nd day after therapy started. Effusion of right knee developed during the 3rd week of therapy. A 20-week follow up period showed no change in joint symptoms.
23 (45 M)	5	6 (14 days) 2 (14 days)	12.0 +	Before After 14th 21st 42nd 63rd 77th 82nd	Cyanosis	0.70 0.96 0.37 0.63 0.59 0.55 0.52	43.8	99	109	Mild progressive rheumatoid arthritis (atypical) with knee effusion of 4 months duration. Nonspecific prostaticitis. Renal stones. Slight improvement during therapy. A 5½ months follow up period showed condition unchanged. Knee effusion and painful shoulders persisted.
24 (31 M)	1/3	6 (15 days)		Before After 7th 14th 21st 42nd	Cyanosis	Not done	58.5	101		Mild typical rheumatoid arthritis (acute onset). No improvement during sulfanilamide therapy. Joint symptoms unchanged during 16-week follow up period.
25 (37 F)	6	6 (14 days)	5.0 +	Before After 7th 14th 21st 30th 42nd	Cyanosis anemia	1.41 0.84 0.58 0.80 0.92 0.93	Not done	Not done	Not done	Moderately severe progressive rheumatoid arthritis (typical) with knee effusions for 4 years. No improvement during therapy and unchanged 4 weeks after cessation of sulfanilamide.
26 (20 M)	4	6 (27 days)	6.4 +	Before After 7th 10th 28th 40th 100th	Cyanosis slight anemia	0.75 1.04 0.78 0.93 1.08 0.74	Not done	Not done	Not done	Moderately severe progressive rheumatoid arthritis (typical) with associated spondylitis. No improvement during or following therapy. Followed 1 month.
30 (31 M)	9	15 (1 day) 8 (8 days)	12.0 +	Before After 14th	Cyanosis fever anorexia nausea rash	0.78 0.71	52.3	100	104	Moderately severe slowly progressive rheumatoid arthritis (typical). Symmetrical joint involvement. Knee effusions of over 4 years duration. Drug omitted after nine days because of appearance of a diffuse maculopapular rash. No improvement in arthritis during or following therapy.
31 (57 M)	5/6	12 (1 day) 7 (1 day) 6 (7 days)	10.0 +	Before After 10th	Cyanosis anorexia nausea fever euphoria	0.21 0.18	45.0	99	101	Very mild slowly progressive rheumatoid arthritis (typical). Symmetrical involvement of shoulders wrists and fingers. No improvement during therapy despite continuous temperature of 102.103°F. No change noted during follow up.

toid arthritis except for the previously mentioned Case 22

These data suggest that a rapid fall in the sedimentation rate in gonorrheal arthritis is indicative of a satisfactory clinical response to the dose of sulfanilamide being administered. If the sedimentation rate remains unchanged, this may indicate inadequate dosage, a resistant gonococcal strain or an incorrect diagnosis

#### EFFECT ON THE GENITOURINARY FOCUS

Gonococci were isolated from the genitourinary tract in 13 of the 14 cases of proved gonorrheal arthritis (Table 2). In 12 of these cases there was marked improvement in the genitourinary

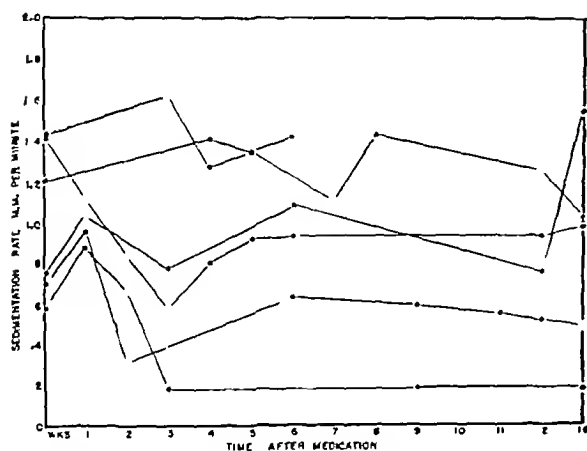

Chart 3 Corrected Sedimentation Rates in Cases of Rheumatoid Arthritis

From this chart one notes that the corrected sedimentation rates of the bloods of patients with rheumatoid arthritis are not altered following the administration of sulfanilamide. The one case in which the sedimentation rate did return to normal (Case 20) developed fever on the fourth day of therapy. It continued between 102 and 103°F during the subsequent eight days.

symptoms and disappearance of the gonococcus after the third day of therapy. Subsequent examinations three to forty-eight weeks after cessation of therapy revealed no clinical or laboratory evidence suggesting a recurrence of the genitourinary infection. In Case 9 the organisms did not disappear from the prostatic secretions until the blood-sulfanilamide level had been raised from 6.5 to 11.5 mg per cent. Gonococci were demonstrable in the prostatic secretions from Case 14 after two periods of large doses of sulfanilamide of seven and fourteen days respectively, during which time the blood-sulfanilamide level varied between 11.7 and 17.4 mg per cent. The genitourinary focus subsequently became negative (Tables 2 and 4). Whether the previous sulfanil-

amide therapy played any part in this cure we are unable to say.

Three additional cases were studied. In 2 the patients had uncomplicated gonorrhea. In 1 there was a complicating ischial bursitis. The case histories are presented in brief because of the ensuing complications.

Case 27 H R, a 44 year-old, married woman, entered the hospital because of proved gonorrheal endocervicitis of 2 months' duration. The temperature was normal prior to treatment.

Beginning 1 day after entry the patient received 1.33 gm of sulfanilamide every 4 hours for 2 days, then 0.66 gm every 4 hours for 12 days, and finally 0.44 gm every 4 hours for 10 days. Four hours after giving the second 1.33-gm. dose the blood sulfanilamide level was 12.6 mg per cent. This level was maintained until the dose was reduced to 0.66 gm every 4 hours. On this dosage it varied between 4.1 and 7.4 mg per cent.

Three sets of pelvic smears obtained after the 4th day of therapy were negative for gonococci. There was no clinical evidence of endocervicitis after the 10th day. The gonococcal complement fixation test never became positive. The carbon-dioxide combining power fell to 45.6 vol per cent. The serum chlorides varied between 97 and 109 milliequivalents. The serum bilirubin was 2.5 mg per cent on the 3rd day of treatment. The hematologic changes observed are presented in Table 3.

Cyanosis was present from the 1st day on. During the first 2 days the patient had severe 'seasickness,' frontal headache and diarrhea. From the 5th to the 16th day of therapy the temperature varied from 101 to 103°F (Chart 5).

**Summary** A patient with proved acute gonorrheal endocervicitis made a complete recovery after 24 days of sulfanilamide therapy. During a 4 week follow-up period she remained well, all clinical examinations and laboratory tests being normal.

Case 28 J McL., a 21-year-old, single man, entered the hospital because of a proved acute gonorrheal urethritis of 2 days duration. The temperature was normal during the entire period of observation.

Beginning 1 day after entry the patient received 1.33 gm of sulfanilamide every 4 hours for 14 days. Forty-eight hours after institution of therapy the urethral discharge disappeared completely. Three prostatic smears obtained after the 2nd day were negative for gonococci. The complement fixation test never became positive. No significant hematologic variations occurred. The carbon dioxide combining power fell to 44.6 vol per cent. The lowest serum chloride was 101 milliequivalents. The serum bilirubin remained unchanged.

Cyanosis was present throughout treatment. On the 14th day the patient developed an acute pharyngitis, fever and a palpable spleen. Twenty-four hours later an enanthem and a faint morbilliform rash appeared. It disappeared 12 hours after discontinuance of the drug. No other toxic symptoms were noted.

**Summary** A patient with acute gonorrheal urethritis made a complete recovery after 14 days of sulfanilamide therapy. During a 2 month follow-up period he has remained cured.

Case 29 G M., a 29 year-old single man, contracted gonorrhea 42 days before entry. Seven days later he developed an ischial bursitis. He received 6 gm of sulfanil-

amide per day, resulting in a blood sulfanilamide level of 95 mg per cent. Two days after institution of therapy the urethral discharge ceased and there was marked reduction in the bursal pain and swelling. No gonococci were demonstrable in three prostatic smears obtained after the 3rd day of therapy. The patient was completely symptom-free in 2 weeks.

*Summary.* A patient with proved gonorrheal prostatitis and an associated ischial bursitis made a complete recovery after 13 days of sulfanilamide treatment.

Thus it will be seen (Table 2) that in 17 of the 18 cases having a proved genitourinary focus no gonococci were isolated after the third day of treatment. These cases remained clinically cured during the three- to forty-eight-week follow-up periods. The 1 failure (Case 14) has been discussed. In another study undertaken to determine what dose of sulfanilamide will cure the greatest number of patients with gonococcal infections in the shortest period of time, we have encountered 2 cases of acute urethritis which did not respond to sulfanilamide. These patients received the drug for fifty-nine and sixty-nine days respectively. During seven days of this therapy the blood-sulfanilamide level was maintained at between 35 and 40 mg per cent. Until the mode of action of sulfanilamide is known, it is impossible to state whether such failures represent special properties of certain gonococcal strains or failure of response in the host. The results in certain cases suggest that insufficient doses of sulfanilamide may interfere with the subsequent effect of large doses. This important point can be determined only by further study.

#### EFFECT ON GONOCOCCAL COMPLEMENT-FIXATION TEST

The gonococcal complement-fixation tests on the blood serums from the 3 patients having proved gonorrheal arthritis with infected synovial fluids never became positive. In Case 2 the synovial-fluid complement-fixation test was positive. The serums from 11 cases of proved gonorrheal arthritis without infected synovial fluids had positive tests. In 6 of these patients the tests became negative in eighteen weeks (Case 4), ten weeks (Case 5), fourteen weeks (Case 6), five weeks (Case 8) and seven weeks (Cases 12 and 13) after the institution of sulfanilamide therapy. In only 1 (Case 18) of the 4 cases of probable gonorrheal arthritis did the test become negative during the time they were followed. In Case 22, with proved gonorrheal prostatitis and urethritis and rheumatoid arthritis, the test remained positive. It became negative within ten and seven weeks respectively in the 2 patients (Cases 21 and 24) with rheumatoid arthritis and probable gonorrheal prostatitis.

Failure to develop positive complement-fixation tests in Cases 1, 2 and 3 suggests that the patients were cured before sufficient antigen had been absorbed.

It is further seen that the serum complement-fixation test for the gonococcus became negative in 9 of the 18 patients having proved (12 cases) or probable (6 cases) gonococcal infections. The fact that the test became negative in such a large percentage of the cases in so short a period of time is further evidence that clinical cures were obtained. Following fever therapy the complement-fixation tests do not become negative in such a large percentage of the cases. They rarely become negative in less than three months' time, and frequently remain positive for as long as six or eighteen months.<sup>3</sup>

#### TOXIC MANIFESTATIONS OBSERVED DURING SULFANILAMIDE THERAPY

During sulfanilamide administration many toxic symptoms appeared. The commonest complaints were vertigo, drowsiness, headache, euphoria, irritability, weakness, nausea, anorexia and at times slight mental confusion. Many patients described their discomfort as being similar to seasickness. Obvious dyspnea was usually present. In no case were these symptoms indicative of serious complications.

*Cyanosis.* A varying degree of cyanosis is observed in all patients receiving large doses of sulfanilamide. It is apparent within the first twenty-four hours after the drug is instituted, and disappears rapidly after it is discontinued. In view of the fact that it has been shown that the oxygen capacity of the blood is not diminished, the cyanosis cannot be considered a contraindication to the continuance of therapy.<sup>37</sup> Hartmann et al.<sup>38, 39</sup> report that the cyanosis disappears if 15 mg of a 10 per cent aqueous solution of methylene blue per kilogram of body weight is given intravenously. They further report that it can be prevented if methylene blue is administered by mouth with each dose of sulfanilamide.

This finding and the demonstration of methemoglobin values as high as 13 mg per cent in patients receiving sulfanilamide have led Hartmann and his associates to conclude that the cyanosis is due to methemoglobin. Other workers<sup>2, 40-44</sup> have reported that the cyanosis is due to either sulfhemoglobin or methemoglobin in the circulating erythrocytes. Posner and his co-workers<sup>45</sup> suggest that such methemoglobin is unstable, thus accounting for the inability to demonstrate regularly its presence in the blood of "sulfanilamide-cyanotic" patients. Marshall and Walzl<sup>37</sup> were able to demonstrate its presence in

the blood of only 1 of 3 patients whose hemoglobin as measured by oxygen capacity corresponded with the theoretical value obtained from the total iron content of the blood. They therefore concluded that methemoglobin plays an insignificant role in the production of the cyanosis. They and others<sup>46</sup> suggest that the erythrocytes, which appear brown even after the blood has been thoroughly aerated, are stained by a pigment formed from sulfanilamide. More recently the same suggestion has been made by Ottenberg and Fox<sup>47</sup> on the basis of experiments in vitro. They demonstrated the development of a violet color when clear solutions of sulfanilamide (10 to 20 mg per cent) were irradiated. When such a solution was added to plasma, the violet color disappeared and the erythrocytes became brown as they do in patients receiving sulfanilamide. These authors venture the supposition that the same violet pigment is made in vivo during the metabolism of sulfanilamide and that it accounts for the cyanosis. There is, however, no actual evidence for such a theory. Further work is necessary before the exact cause of the cyanosis can be stated.

*"Acidosis"* Since the original report of Southworth,<sup>34</sup> most writers have noted a reduction in the plasma carbon-dioxide combining power. We have observed similar changes. Often the values obtained were within the normal range, but in every case the premedication values were higher than those obtained during therapy. The lowest serum carbon-dioxide combining power observed was 41 vol per cent (Case 12). The average reduction observed was 10 vol per cent. This reduction of the carbon-dioxide combining power occurred even though the patients received amounts of sodium bicarbonate equal to the sulfanilamide dosage.

This lone blood chemical alteration has been interpreted as signifying the existence of acidosis. That such might not be the case was first suggested by Hartmann and his co-workers.<sup>38, 39</sup> They observed that the hyperventilation resulting from moderately large doses of sulfanilamide simulated the dyspnea of acidosis, yet only moderate reductions (15 to 20 vol per cent) of carbon-dioxide content of the blood were demonstrable. Further studies revealed that coincident with the fall in the carbon-dioxide content of the serum there occurred a rise in serum pH and the production of an alkaline urine. These findings led the investigators to conclude that the changes in the acid-base equilibrium represented a carbon-dioxide-deficit type of alkalosis secondary to primary hyperventilation, and not acidosis. They have suggested that the routine administration of al-

kali in conjunction with sulfanilamide is not indicated.

Direct determinations made in this laboratory are in agreement with the theory proposed by Hartmann and his associates, namely, that hyperventilation occurs after the administration of large doses of sulfanilamide.<sup>48</sup> Whether or not primary hyperventilation is the sole cause for the observed changes in acid-base equilibrium is a question requiring further study. Detailed studies of the electrolyte metabolism reveal that the first effects noted following the administration of sulfanilamide are a striking increase in urinary total base excretion (chiefly sodium), a marked reduction in ammonia output and a strongly alkaline urine (pH 7.4 to 7.8). The serum-sodium concentration falls 5 or 6 milliequivalents. There occurs a corresponding lowering of the serum carbon-dioxide content. Within a few days the sodium and ammonia excretion and the urinary pH return to pre-treatment values despite continuance of the drug. The lower serum-sodium concentrations, however, persist so long as the drug is given (twenty-eight days in one experiment). When it is discontinued the reverse phenomena are observed: sodium is retained, the serum sodium concentration returns to its normal level, the excretion of ammonia is increased and the urine becomes acid. The excretion of potassium follows a course similar to that of sodium but of considerably less magnitude.<sup>48</sup> These and other observations on the electrolyte metabolism will be published in detail at a later date.

*Anemia* Severe hemolytic anemias, such as have been reported as occurring on the third to fifth day of treatment,<sup>2, 3, 49-51</sup> were not observed in any of these patients. Elevation of the serum bilirubin occurred in Case 27 on the fourteenth day of therapy; it was normal on the twentieth day. No other cases of bilirubinemia were observed. Jaundice was never noted in Case 27 or in any of the other cases. Urobilinuria was never found. Thirteen of the 27 patients developed a moderate to marked anemia (Table 3 and Chart 4). In these patients there occurred a progressive fall in the erythrocyte counts, the lowest levels being reached at the time therapy was discontinued, except in Case 2, where the lowest count was observed seven days later. In most cases the severe anemias were characterized by color and volume indices over 1.0. The stained blood films showed the red cells to be well filled with hemoglobin, the predominant cells being macrocytes, although microcytes and immature erythrocytes were seen. Reticulocyte responses varying from 5 to 22 per cent were observed in 9

patients The counts were highest when the erythrocyte levels were lowest Following the reticulocytosis there occurred a spontaneous rise in the erythrocyte counts to the pre-treatment level The patients receiving treatment other than transfusions for their anemia responded no more rapidly than did those who were untreated As can be seen from Table 3, the severity of the anemia was not necessarily related to the

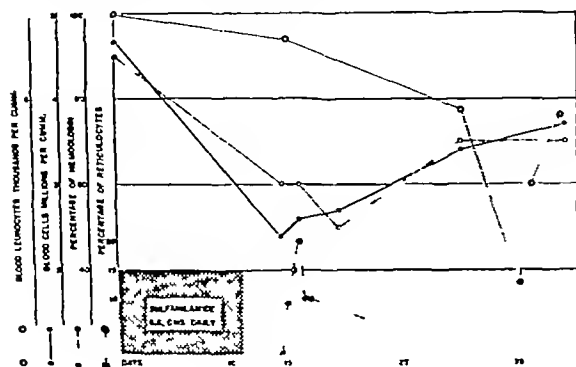

Chart 4 Case 3

This chart represents the hematologic changes encountered following the administration of sulfanilamide. It will be noted that spontaneous reticulocytosis took place after the maximal drop in the erythrocyte count had occurred. The leukopenia was observed twenty-two days after the cessation of sulfanilamide therapy. From Table 3 one notes that this type of sub-clinical hemolytic anemia was encountered in 13 of the 28 patients treated with sulfanilamide.

amount of sulfanilamide administered or to the length of time it was given. In some cases a leukocytosis developed subsequent to the administration of the drug. The total leukocyte count in Case 2 reached 28,000.

The hematologic changes observed in these patients suggest that sulfanilamide therapy may cause a progressive sub-clinical hemolytic anemia as well as the severe acute types. The mechanism of production of such anemias is unknown. That they do not represent a true idiosyncrasy has been proved by Long and Bliss.<sup>3</sup> The red blood cells in certain individuals may be rendered more susceptible to hemolysis by sulfanilamide because of the existing infection. Because this type of anemia develops in such a large percentage of the patients receiving large doses of sulfanilamide, frequent blood examinations should be made during and following the period of therapy. Patients with severe anemias, requiring sulfanilamide treatment, should be transfused prior to or coincident with the administration of the drug. If severe anemias occur, the drug should be discontinued and the patient transfused.

**Leukopenia** In 2 patients (Cases 3 and 4) there occurred marked reductions in the total number

of leukocytes (Table 3 and Chart 4). In Case 3 a leukopenia of 1800 was observed twenty-two days after discontinuance of the drug, whereas in Case 4 the leukocyte count fell to 2800 on the twenty-fifth day of therapy. The percentage of polymorphonuclear leukocytes never fell below 43 per cent. The leukocyte counts returned to normal in a few days without the employment of any of the so-called specific forms of therapy. Here, as in the case of the anemia, there was no relation to the amount of the drug given or to the length of time it was administered. The exact mechanism responsible for such leukopenias is as yet unknown. That it is not the same type as results from amidopyrine is suggested by the

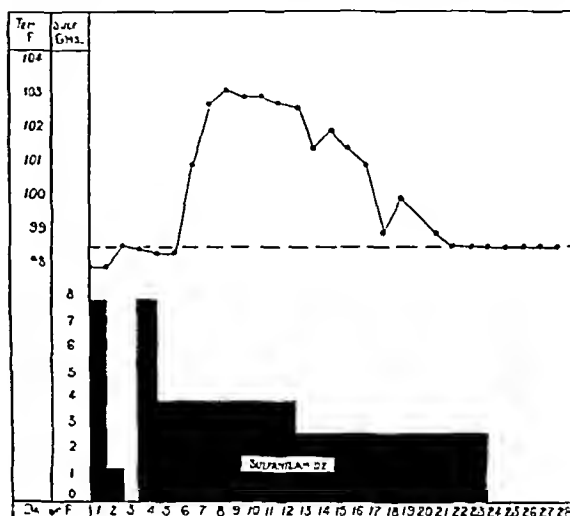

Chart 5 Case 27

This chart illustrates the continuous type of temperature encountered in some patients while receiving sulfanilamide. The temperature always disappears when the drug is discontinued. In this instance it disappeared before the drug was discontinued.

fact that readministration of the drug to such patients following a return of the leukocytes to normal does not necessarily result in reproduction of the leukopenia.<sup>52</sup> The occurrence of agranulocytosis as well as leukopenia following sulfanilamide therapy has been reported by other workers.<sup>2, 3, 8, 49-56</sup> In some of these cases severe infections may have been a predisposing factor. Allen and Short<sup>57</sup> observed 1 patient with agranulocytosis who made a spontaneous recovery. In a few cases death has occurred.<sup>58-63</sup> These findings suggest the necessity of frequent leukocyte and differential counts during and following the administration of the drug.

**Fever** Six patients (Cases 1, 11, 20, 27, 30 and 31) developed a sustained fever on the fourth or fifth day of therapy, which continued until sulfanilamide was discontinued or the dose was reduced (Chart 5). In Case 20 fever developed on

patients The counts were highest when the erythrocyte levels were lowest Following the reticulocytosis there occurred a spontaneous rise in the erythrocyte counts to the pre-treatment level The patients receiving treatment other than transfusions for their anemia responded no more rapidly than did those who were untreated As can be seen from Table 3, the severity of the anemia was not necessarily related to the

of leukocytes (Table 3 and Chart 4) In Case 3 a leukopenia of 1800 was observed twenty-two days after discontinuance of the drug, whereas in Case 4 the leukocyte count fell to 2800 on the twenty-fifth day of therapy The percentage of polymorphonuclear leukocytes never fell below 43 per cent The leukocyte counts returned to normal in a few days without the employment of any of the so-called specific forms of therapy Here, as in the case of the anemia, there was no relation to the amount of the drug given or to the length of time it was administered The exact mechanism responsible for such leukopenias is as yet unknown That it is not the same type as results from amidopyrine is suggested by the

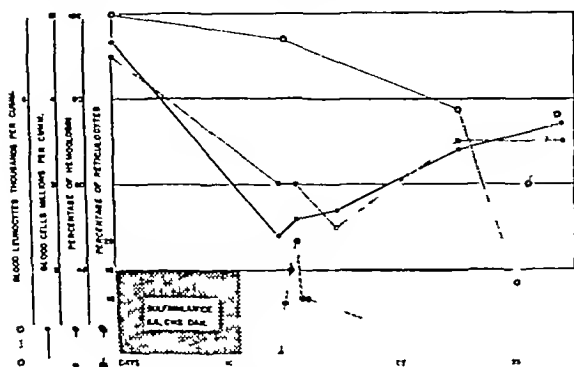

Chart 4 Case 3

*This chart represents the hematologic changes encountered following the administration of sulfanilamide. It will be noted that spontaneous reticulocytosis took place after the maximal drop in the erythrocyte count had occurred. The percentage of polymorphonuclear leukocytes never fell below 43 per cent. The leukocyte counts returned to normal in a few days without the employment of any of the so-called specific forms of therapy. Here, as in the case of the anemia, there was no relation to the amount of the drug given or to the length of time it was administered. The exact mechanism responsible for such leukopenias is as yet unknown. That it is not the same type as results from amidopyrine is suggested by the

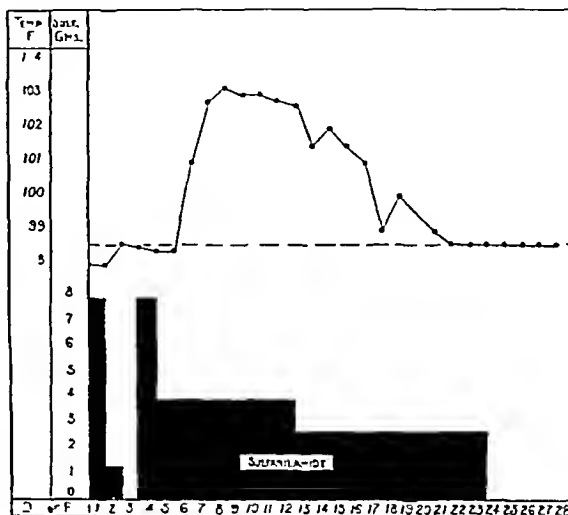

Chart 5 Case 27

This chart illustrates the continuous type of temperature encountered in some patients while receiving sulfanilamide. The temperature always disappears when the drug is discontinued. In this instance it disappeared before the drug was discontinued.

fact that readministration of the drug to such patients following a return of the leukocytes to normal does not necessarily result in reproduction of the leukopenia.<sup>52</sup> The occurrence of agranulocytosis as well as leukopenia following sulfanilamide therapy has been reported by other workers.<sup>2, 3, 8, 49-56</sup> In some of these cases severe infections may have been a predisposing factor. Allen and Short<sup>57</sup> observed 1 patient with agranulocytosis who made a spontaneous recovery. In a few cases death has occurred.<sup>58-63</sup> These findings suggest the necessity of frequent leukocyte and differential counts during and following the administration of the drug.

**Fever.** Six patients (Cases 1, 11, 20, 27, 30 and 31) developed a sustained fever on the fourth or fifth day of therapy, which continued until sulfanilamide was discontinued or the dose was reduced (Chart 5). In Case 20 fever developed on

the blood of only 1 of 3 patients whose hemoglobin as measured by oxygen capacity corresponded with the theoretical value obtained from the total iron content of the blood. They therefore concluded that methemoglobin plays an insignificant role in the production of the cyanosis. They and others<sup>46</sup> suggest that the erythrocytes, which appear brown even after the blood has been thoroughly aerated, are stained by a pigment formed from sulfanilamide. More recently the same suggestion has been made by Ottenberg and Fox<sup>47</sup> on the basis of experiments in vitro. They demonstrated the development of a violet color when clear solutions of sulfanilamide (10 to 20 mg per cent) were irradiated. When such a solution was added to plasma, the violet color disappeared and the erythrocytes became brown as they do in patients receiving sulfanilamide. These authors venture the supposition that the same violet pigment is made in vivo during the metabolism of sulfanilamide and that it accounts for the cyanosis. There is, however, no actual evidence for such a theory. Further work is necessary before the exact cause of the cyanosis can be stated.

*"Acidosis."* Since the original report of Southworth,<sup>34</sup> most writers have noted a reduction in the plasma carbon dioxide combining power. We have observed similar changes. Often the values obtained were within the normal range, but in every case the premedication values were higher than those obtained during therapy. The lowest serum carbon-dioxide combining power observed was 41 vol per cent (Case 12). The average reduction observed was 10 vol per cent. This reduction of the carbon-dioxide combining power occurred even though the patients received amounts of sodium bicarbonate equal to the sulfanilamide dosage.

This lone blood chemical alteration has been interpreted as signifying the existence of acidosis. That such might not be the case was first suggested by Hartmann and his co-workers.<sup>18, 39</sup> They observed that the hyperventilation resulting from moderately large doses of sulfanilamide simulated the dyspnea of acidosis, yet only moderate reductions (15 to 20 vol per cent) of carbon-dioxide content of the blood were demonstrable. Further studies revealed that coincident with the fall in the carbon-dioxide content of the serum there occurred a rise in serum pH and the production of an alkaline urine. These findings led the investigators to conclude that the changes in the acid base equilibrium represented a carbon-dioxide-deficit type of alkalosis secondary to primary hyperventilation, and not acidosis. They have suggested, that the routine administration of al-

kali in conjunction with sulfanilamide is not indicated.

Direct determinations made in this laboratory are in agreement with the theory proposed by Hartmann and his associates, namely, that hyperventilation occurs after the administration of large doses of sulfanilamide.<sup>48</sup> Whether or not primary hyperventilation is the sole cause for the observed changes in acid-base equilibrium is a question requiring further study. Detailed studies of the electrolyte metabolism reveal that the first effects noted following the administration of sulfanilamide are a striking increase in urinary total base excretion (chiefly sodium), a marked reduction in ammonia output and a strongly alkaline urine (pH 7.4 to 7.8). The serum-sodium concentration falls 5 or 6 milliequivalents. There occurs a corresponding lowering of the serum carbon-dioxide content. Within a few days the sodium and ammonia excretion and the urinary pH return to pre-treatment values despite continuance of the drug. The lower serum-sodium concentrations, however, persist so long as the drug is given (twenty-eight days in one experiment). When it is discontinued the reverse phenomena are observed: sodium is retained, the serum sodium concentration returns to its normal level, the excretion of ammonia is increased and the urine becomes acid. The excretion of potassium follows a course similar to that of sodium but of considerably less magnitude.<sup>48</sup> These and other observations on the electrolyte metabolism will be published in detail at a later date.

*Anemia.* Severe hemolytic anemias, such as have been reported as occurring on the third to fifth day of treatment,<sup>2, 3, 49-51</sup> were not observed in any of these patients. Elevation of the serum bilirubin occurred in Case 27 on the fourteenth day of therapy, it was normal on the twentieth day. No other cases of bilirubinemia were observed. Jaundice was never noted in Case 27 or in any of the other cases. Urobilinuria was never found. Thirteen of the 27 patients developed a moderate to marked anemia (Table 3 and Chart 4). In these patients there occurred a progressive fall in the erythrocyte counts, the lowest levels being reached at the time therapy was discontinued, except in Case 2, where the lowest count was observed seven days later. In most cases the severe anemias were characterized by color and volume indices over 1.0. The stained blood films showed the red cells to be well filled with hemoglobin, the predominant cells being macrocytes, although microcytes and immature erythrocytes were seen. Reticulocyte responses varying from 5 to 22 per cent were observed in 9

patients The counts were highest when the erythrocyte levels were lowest Following the reticulocytosis there occurred a spontaneous rise in the erythrocyte counts to the pre-treatment level The patients receiving treatment other than transfusions for their anemia responded no more rapidly than did those who were untreated As can be seen from Table 3, the severity of the anemia was not necessarily related to the

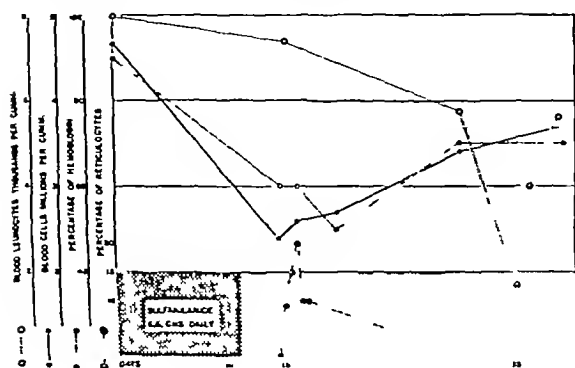

Chart 4 Case 3

This chart represents the hematologic changes encountered following the administration of sulfanilamide. It will be noted that spontaneous reticulocytosis took place after the maximal drop in the erythrocyte count had occurred. The leukopenia was observed twenty-two days after the cessation of sulfanilamide therapy. From Table 3 one notes that this type of sub-clinical hemolytic anemia was encountered in 13 of the 28 patients treated with sulfanilamide.

amount of sulfanilamide administered or to the length of time it was given. In some cases a leukocytosis developed subsequent to the administration of the drug. The total leukocyte count in Case 2 reached 28,000.

The hematologic changes observed in these patients suggest that sulfanilamide therapy may cause a progressive sub-clinical hemolytic anemia as well as the severe acute types. The mechanism of production of such anemias is unknown. That they do not represent a true idiosyncrasy has been proved by Long and Bliss.<sup>3</sup> The red blood cells in certain individuals may be rendered more susceptible to hemolysis by sulfanilamide because of the existing infection. Because this type of anemia develops in such a large percentage of the patients receiving large doses of sulfanilamide, frequent blood examinations should be made during and following the period of therapy. Patients with severe anemias, requiring sulfanilamide treatment, should be transfused prior to or coincident with the administration of the drug. If severe anemias occur, the drug should be discontinued and the patient transfused.

**Leukopenia** In 2 patients (Cases 3 and 4) there occurred marked reductions in the total number

of leukocytes (Table 3 and Chart 4). In Case 3 a leukopenia of 1800 was observed twenty-two days after discontinuance of the drug, whereas in Case 4 the leukocyte count fell to 2800 on the twenty-fifth day of therapy. The percentage of polymorphonuclear leukocytes never fell below 43 per cent. The leukocyte counts returned to normal in a few days without the employment of any of the so-called specific forms of therapy. Here, as in the case of the anemia, there was no relation to the amount of the drug given or to the length of time it was administered. The exact mechanism responsible for such leukopenias is as yet unknown. That it is not the same type as results from amidopyrine is suggested by the

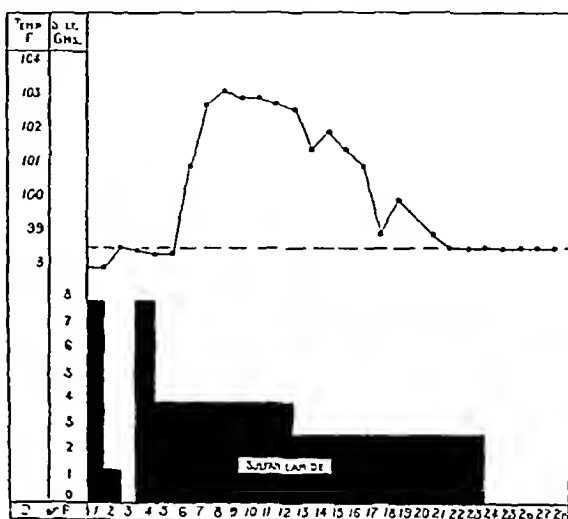

Chart 5 Case 27

This chart illustrates the continuous type of temperature encountered in some patients while receiving sulfanilamide. The temperature always disappears when the drug is discontinued. In this instance it disappeared before the drug was discontinued.

fact that readministration of the drug to such patients following a return of the leukocytes to normal does not necessarily result in reproduction of the leukopenia.<sup>52</sup> The occurrence of agranulocytosis as well as leukopenia following sulfanilamide therapy has been reported by other workers.<sup>2, 3, 9, 49-56</sup> In some of these cases severe infections may have been a predisposing factor. Allen and Short<sup>57</sup> observed 1 patient with agranulocytosis who made a spontaneous recovery. In a few cases death has occurred.<sup>58-63</sup> These findings suggest the necessity of frequent leukocyte and differential counts during and following the administration of the drug.

**Fever** Six patients (Cases 1, 11, 20, 27, 30 and 31) developed a sustained fever on the fourth or fifth day of therapy, which continued until sulfanilamide was discontinued or the dose was reduced (Chart 5). In Case 20 fever developed on

the fourth day and continued at 102 or 103°F until the drug was discontinued on the twelfth day. Such febrile responses have been observed by others,<sup>3 14 64 65</sup> and are thought to represent a specific reaction to the drug. Therefore the persistence of fever without clinical evidence of infection should always lead one to suspect that it is due to sulfanilamide. If such is the case, omission of the drug should result in subsidence of the fever.

**Skin Reactions** In Cases 20 and 30 a morbilliform rash developed on the fourteenth day of therapy. There was an associated fever, cervical adenopathy, enanthem of the pharyngeal walls, and a palpable spleen. The rash faded twelve hours after discontinuance of sulfanilamide. A much more marked rash was observed in Case 30. Similar skin eruptions have been described.<sup>3 64-72</sup> They appear during the first or second week of therapy, and disappear twenty-four to forty-eight hours after discontinuance of sulfanilamide.

One patient (Case 5), following exposure to sunlight, developed an erythredema of one side of the face and the dorsal surfaces of the hands and wrists. This reaction disappeared five days later, even though the dosage of sulfanilamide remained unchanged. Previous reports have called attention to similar skin reactions following exposure to sunlight.<sup>66 68 71</sup> Because of this risk, it would seem unwise to allow patients receiving sulfanilamide to expose themselves to the direct rays of the sun.

Two patients (Cases 11 and 18) developed generalized urticaria on the tenth day of therapy, in each case it disappeared three days after the omission of sulfanilamide. In Case 18 there was a similar experience three weeks prior to entry, after the giving of 5 gr. of sulfanilamide four times a day for twenty-one days.

Such skin manifestations do not represent serious complications, and require no treatment other than discontinuance of sulfanilamide therapy. The manner of their production is as yet not understood.

#### MODE OF ACTION OF SULFANILAMIDE

The exact mode of action of sulfanilamide in bacterial infections has not been established. Keefer<sup>6</sup> states that the blood of patients with gonococcal infections becomes bacteriocidal as well as bacteriostatic following the administration of sulfanilamide for a few days. Further studies of this type must be undertaken. That sulfanilamide when administered in large doses has a specific effect on the gonococcus is well demonstrated by the data herein presented.

Similar observations concerning the action of

sulfanilamide in streptococcal infections have been made. At the present time it is impossible to say whether or not its dramatic clinical results are due solely to the slightly increased bacteriocidal effect. It is apparent, however, that sulfanilamide therapy offers a method of approach to the study of the conditions responsible for the healing of infectious diseases.

#### DISCUSSION

From the results obtained in this group of patients it appears that if the highest percentage of clinical cures is to be obtained, sulfanilamide should be administered in large doses. A constant fluid intake should be maintained. It is extremely important that one sixth of the total calculated dose be given every four hours, day and night, if constant blood-sulfanilamide levels are to be maintained throughout each twenty-four-hour period. This method of administration will maintain levels varying from 5 to 10 mg per cent. If this dose is to be therapeutically effective, definite evidence of improvement should be apparent within forty-eight to seventy-two hours. Those cases that do not experience immediate improvement will not be affected by sulfanilamide therapy until the dose is increased. From our experience this group tends to run lower blood-sulfanilamide levels (5.0 to 7.5 mg per cent). If this is found to be the case, administration of one third the total calculated dose at two successive four-hour periods, followed by one sixth the calculated twenty-four hour dose every four hours, will usually suffice to raise the blood-sulfanilamide level above 10 mg per cent. Such blood levels may prove to be therapeutically effective when the lower levels are seemingly ineffective. Further studies may eventually prove that the highest percentage of cures will be obtained in those patients whose blood-sulfanilamide level is kept at or above 10 mg per cent.

Despite the fact that striking clinical improvement and sterilization of infected synovial fluids may occur as early as forty-eight to seventy-two hours after institution of sulfanilamide therapy, we have in most cases administered large doses for a period of two weeks or longer in order to obtain the largest possible number of clinical cures. Recent experience suggests that large doses for short periods of time, seven days or less, may suffice. Further studies, however, are necessary in order to establish with certainty that shorter periods of therapy and smaller doses will allow for the same percentage of clinical cures as we have observed. That small doses (10 to 15 gr. three or four times a day, during the day only) may not effect clinical cures is well illustrated by

the 4 patients (Cases 12, 13, 14 and 18) who were so treated prior to hospital entry. The data from these cases further suggest that small doses may increase the resistance of the gonococcus to subsequent sulfanilamide therapy.

Shorter periods of therapy with large doses might aid materially in reducing the frequency of the various toxic manifestations. These, however, except for the rare cases of agranulocytosis, do not represent serious complications, providing they are watched for and recognized early in order that appropriate treatment may be instituted at once. In most cases discontinuance of sulfanilamide and the forcing of fluids (5000 cc. the first day) will suffice. In the case of severe anemias, leukopenia or agranulocytosis, transfusions may be necessary. Frequent urinalyses and serum non-protein nitrogens—and phenolsulfonephthalein and urine-concentration tests in some cases—have failed to reveal any evidence of renal impairment or irritation following the use of this drug. No evidence of hepatic impairment was noted in any of the cases so studied. In the rare cases with renal impairment requiring sulfanilamide therapy the amount of the drug required must be established by frequent blood-sulfanilamide determinations. In such cases one should aim for a level of 10 mg per cent.

From our experience in treating gonorrheal arthritis it is obvious that the best end results will be obtained in cases where therapy is instituted before joint destruction has occurred. It is unreasonable to expect prompt and complete subsidence of the soft-tissue inflammatory changes, removal of the fibrosed tissue and restoration of destroyed joint surfaces encountered in the subacute and chronic cases of gonorrheal arthritis. It is quite amazing to witness the restoration to normal of a case of severe acute gonorrheal arthritis so soon after the administration of sulfanilamide. From our data it appears that a gonococcal focus of long duration responds as promptly as does one of short duration. Further study of a large group of patients having infected synovial fluids is necessary in order to establish what percentage can be cured with large doses of sulfanilamide. From the results observed we do not claim that all cases of gonorrhea will be cured, but we believe that early diagnosis and treatment with large amounts of the drug will undoubtedly give the best results.

The specific value of any therapeutic measure can be established only if one is able to demonstrate that the clinical course of the disease is strikingly altered in a large percentage of cases. The results herein reported, as well as those of other workers, indicate clearly the effect of sulfanilamide on gonorrheal arthritis. We have

never observed this prompt arrest and subsidence of the inflammatory changes, including joint pain, to take place so regularly with other therapeutic measures, including fever therapy. This quick response of an active gonorrheal arthritis is of itself sufficient to allow one to conclude that sulfanilamide exerts a specific chemotherapeutic effect on the gonococcus.

Additional studies must be undertaken in order to establish (1) the amount of sulfanilamide necessary to cure the majority of the patients with gonorrheal infections, (2) the length of time the drug should be administered, (3) the dose required for those patients who do not respond to the usual dosage, (4) the length of time the drug should be continued in the absence of clinical improvement, (5) whether insufficient initial doses influence the efficacy of larger doses given subsequently, (6) whether some strains of gonococci are sulfanilamide-resistant, and (7) what role the immunologic response of the host plays in the therapeutic effectiveness of sulfanilamide. The answers to such questions will not only increase the usefulness of sulfanilamide therapy, but also will add to our general knowledge concerning the healing of infectious diseases.

#### SUMMARY

From the results obtained in treating 14 cases of proved and 4 of probable gonorrheal arthritis, 2 cases of gonorrhea, and 2 cases of proved and 2 of probable gonococcal prostatitis, the following conclusions seem justified.

Sulfanilamide administered in large doses for two or more weeks appears to be a specific chemotherapeutic agent for certain strains of gonococci because

1. Infected synovial fluids can be sterilized in forty-eight to seventy-two hours after institution of therapy.
2. In 17 of the 18 cases having a proved genitourinary focus, no gonococci were found after the third day of treatment. These cases remained clinically cured during the follow-up periods.
3. The gonococcal complement-fixation test failed to become positive in 3 cases of gonorrheal arthritis with infected synovial fluids. In 9 of the remaining 18 cases the complement-fixation test became negative.
4. Nine of the proved and 2 of the probable cases of gonorrheal arthritis showed striking clinical improvement in forty-eight to seventy-two hours after institution of therapy.

- 5 The end results in the 14 proved and the 4 probable cases of gonorrheal arthritis were more satisfactory and took place in shorter periods of time than occurs with other forms of therapy

The toxic manifestations resulting from the administration of large doses of sulfanilamide are readily recognized. They do not represent serious complications (except for the hematologic changes), and respond promptly to discontinuance of the drug.

A slow, progressive, sub-clinical hemolytic anemia occurred in 13 of the 28 patients. Leukopenia was observed in 2 cases.

The erythrocyte sedimentation rates fell rapidly in the cases of gonorrheal arthritis showing striking and immediate relief.

The largest percentage of clinical cures will be obtained in patients with gonococcal infections if sulfanilamide in doses sufficient to maintain a blood-sulfanilamide level of 10 mg per cent or higher for seven or more days is administered early.

The clinical course of rheumatoid arthritis is not affected by large doses of sulfanilamide. The erythrocyte sedimentation rate remained unchanged in 9 of the 10 cases treated.

## PEPTIC ULCER CONSIDERED FROM A SURGICAL POINT OF VIEW\*

ARTHUR W ALLEN, M.D† and CLAUDE E WELCH, M.D‡

BOSTON

THE treatment of patients with peptic ulcer has undergone profound changes since twenty years ago. At that time most physicians, influenced by the enthusiasm of surgeons of an earlier day whose brilliant results with gastroenterostomy had enabled Moynihan<sup>1</sup> to say, "No operation in surgery has produced more striking or swifter results," considered peptic ulcer to be a surgical disease which responded satisfactorily to this form of treatment. Not many years elapsed, however, before other surgical procedures were recommended, for it was soon demonstrated that gastrojejunostomy should not be employed as a routine procedure. Plastic operations on the pylorus, such as the pyloroplasty of Finney and the gastroduodenostomy of Wilkie, gained favor, but after more extensive experience, these too were found to have definite disadvantages. Later, resection of the pylorus and finally subtotal resection of the stomach were developed.

Coincidentally with these changes in surgical procedure, the medical treatment of peptic ulcer developed, so that the management of a high proportion of cases without surgical intervention is now entirely satisfactory. Consequently the treatment of this disease has come to be considered more commonly a medical problem and less frequently a surgical one. In the Massachusetts General Hospital such patients are now followed in a combined medical and surgical clinic.

All these changes in treatment have been reflected in the cases treated at this hospital. Through study of the records of about 2700 cases

of peptic ulcer treated here during the last fifteen years, we have reached definite conclusions with respect to the proper surgical treatment of this disease. The indications and types of surgery that have been employed are summarized in the accompanying tables.

The end results of all cases treated by surgery prior to 1923 were appraised by Fremont-Smith and McIver<sup>2</sup> in 1929. At that time, gastroenterostomy was employed as a specific measure. They found that approximately 80 per cent of patients were relieved by this operation. It is of interest that nearly 80 per cent of all ulcer patients seen in this hospital in the fifteen years since 1923 were relieved by medical means (Table 1). It seems

Table 1 Type of Treatment Received at the Massachusetts General Hospital (1922-1936) by 2726 Patients with Duodenal Ulcer

YEARS	MEDICALLY TREATED CASES			SURGICALLY TREATED CASES		
	NUMBER		PERCENTAGE	NUMBER PERCENTAGE		
	O P D	House		Total	PERCENTAGE	
1922 1926	440	250	699	76.8	211	23.2
1927 1931	322	377	699	80.5	170	19.5
1932 1936	259	481	740	78.2	207	21.8
	Totals		2138	78.4	588	21.6

entirely possible that the 20 per cent of patients now not rendered symptom-free by medical measures would not have been helped by gastroenterostomy in earlier years.

Within the last fifteen years the percentage of patients requiring surgical treatment has averaged close to 20. The most important evidence presented in Table 1 is that peptic ulcer has come to be regarded as a disease that should be appraised critically in the hospital wards rather

\*Presented at the annual meeting of the Massachusetts Medical Society Boston, June 1, 1938.

†Chief of the East Surgical Service, Massachusetts General Hospital, lecturer in surgery, Harvard Medical School.

‡Assistant in surgery, Massachusetts General Hospital.

than be treated solely in the Out Patient Department, as was the case in earlier years

It is convenient to classify the cases which come to require operation according to the following indications: acute perforation, cicatricial obstruction, profuse bleeding and pain intractable to medical treatment. Although the total number of cases requiring surgery has not changed, a glance at Table 2 will show that the number of patients

Table 2 *Indications for Operation in the 588 Patients with Duodenal Ulcer*

YEARS	INDICATIONS				
	ACUTE PERFORATION	CICATRICIAL OBSTRUCTION	PROFUSE BLEEDING	INTRACTABLE PAIN	MISCELLANEOUS
1922-1926	32	67	6	101	5
1927-1931	55	59	6	45	5
1932-1936	56	67	24	42	18
Totals	143	193	36	188	28
Percentages of grand total	24.3	32.8	6.1	31.9	4.7

operated on for different indications has been greatly modified. Thus in late years the number of patients operated on for so-called intractable pain has diminished by 50 per cent. On the other hand, the significance of massive bleeding as an indication for surgery has been appreciated only recently, and the number of operations for this complication has increased.

#### ACUTE PERFORATION

It is well established that patients with acute perforation of a peptic ulcer should be operated on without delay. There are a few with small perforations which become walled off spontaneously, either by omentum or by a neighboring viscus, who will survive without operation. The selection of such cases is too difficult at present, and in case of doubt patients should be given a better chance for recovery by early surgical intervention.

The surgery in nearly every case need include no more than simple closure of the perforation. This may be done by placing sutures in normal tissue on either side of the ulcer in such a manner that constriction is avoided, and tying them together. Often this method is impossible because of the size of the ulcer, and it is necessary to use an omental tab to cover the perforation, holding it there by loosely tied sutures passed through the edges of the ulcer. This procedure is highly recommended by Roscoe Graham<sup>3</sup>. He has used it with such success that we are inclined to employ it in all perforations. Constriction of the duodenum rarely occurs when this is done. In any event, it must be recognized that while the pylorus may seem to be obstructed, most of the swelling is due to edema, and a superimposed gastrojejunostomy

for relief of the obstruction is very rarely indicated. An attempt to cure the ulcer by means of gastrojejunostomy, pyloroplasty or partial gastrectomy at the time of suture of the perforation is generally considered unjustifiable. Not only are these operations often unsatisfactory, but they add a considerably increased hazard to an already precarious condition. Furthermore, it must be remembered that many patients are cured by the fibrosis of the ulcer which follows perforation and suture.

#### CICATRICIAL OBSTRUCTION

Obstruction of the pylorus due to peptic ulcer may be produced either by edema due to an active ulcer or by fibrosis and contraction about the pylorus. The distinction is not always easy to make, but is exceedingly important as a means of determining proper treatment. The acute ulcer is usually characterized by the occurrence of typical ulcer pain, in addition to the vomiting characteristic of obstruction. Prompt relief usually follows decompression of the stomach with a Levine tube, a proper diet and the administration of belladonna. Operation is contraindicated in these cases, if it can possibly be avoided, because the extensive periduodenal inflammation prevents any direct attack on the ulcer. If operation cannot be avoided and there is excessive reaction around the duodenum, a conservative operation such as gastroduodenostomy is indicated, in the hope that later a subtotal gastrectomy may be safely done.

On the other hand, there is a large group of patients with pyloric obstruction due to the formation of dense scar tissue, to whom the administration of anti-spasmodics brings no relief. This condition may develop in young patients, but is much commoner in older ones. It is usually associated with low gastric acidity. Gastroenterostomy in this group usually results in complete relief from symptoms, for the simple mechanical problem of pyloric obstruction is answered, and there is practically no danger of late gastrojejunal ulcer.

#### PROFUSE BLEEDING

Two distinct problems are encountered in this group of cases. One is presented by patients who enter the hospital bleeding profusely, the other by those who have had one or more severe hemorrhages but are in good physical condition at entry.

Treatment of profuse bleeding must be considered without delay. It has been shown from a study of the Massachusetts General Hospital cases by Allen<sup>4</sup> that death occurs in one third of such patients who are fifty years of age or over, but in slightly less than 5 per cent of those under that

age This difference we attribute to the sclerosis of the eroded vessels in older patients, on account of which thrombosis is accomplished with much more difficulty than in younger ones

It has also been shown conclusively by Finsterer,<sup>5</sup> and in a small series of cases at the Massachusetts General Hospital,<sup>6</sup> that operation performed more than forty-eight hours after onset of the hemorrhage carries an excessively high mortality On the other hand, if resection can be done within forty-eight hours there is little more risk than with an ordinary resection Certainly the mortality will be less in the older age group if they are operated on than if they are allowed to bleed Younger patients should be treated conservatively, with operation reserved for a later date

This leads us to a consideration of the patient who has had one or more massive hemorrhages but is admitted with a quiescent ulcer There is great variation of opinion on this subject Jordan and Kiefer<sup>7</sup> have shown that such patients are kept symptom-free with extreme difficulty, 40 per cent failing to get relief from medical measures after one hemorrhage, and 85 per cent after two This group, then, merges with our fourth group of ulcers unresponsive to medical care which require operation

We conclude from a study of our cases that one massive hemorrhage is an indication for operation in patients over fifty A single hemorrhage in the younger group demands a careful medical regime If ulcer symptoms persist, or if a second massive hemorrhage occurs, operation is indicated

The type of operation to be employed depends on the presence or absence of acute bleeding A method of approach useful in dealing with acute massive hemorrhage has been described by Allen,<sup>8</sup> in it bleeding is controlled by the finger, while all vessels leading into the ulcer are ligated in normal tissues If the operation is performed after the subsidence of the acute hemorrhage, a subtotal resection of the stomach should be done If possible the ulcer should be resected, if not, the vessels supplying it should be ligated The earlier procedure of gastroenterostomy for massive bleeding has been found to be unsatisfactory

#### PAIN INTRACTABLE TO MEDICAL TREATMENT

Although medical treatment of peptic ulcer is much more satisfactory than it was formerly, a certain number of patients still fail to respond to it Some have persistent pain despite the fact that they are supervised carefully in the hospital Others improve in the hospital but have a recurrence of symptoms soon after they leave, owing to an unhappy home environment or to excessive

business worries Some find it impossible to continue the proper medical diet outside the hospital Most of these patients have repeated hospital admissions, surgical intervention finally becoming necessary

The number of patients classed as intractable to medical treatment is less than half what it was fifteen years ago In the early years of our survey, posterior gastroenterostomy was employed as a routine operative treatment Quite obviously many of the successful gastroenterostomies in this group in early years were performed on patients who now might be kept comfortable without surgery On the other hand, the patients at present classed as intractable comprise one of the most serious challenges to the gastric surgeon, it is here that the poor results of gastroenterostomy are found Duodenal ulcers on the posterior wall and associated with bleeding, deeply penetrating lesions, multiple ulcers, gastric ulcers that do not decrease in size under treatment, those with an extensive gastritis and those with a high gastric acidity, all demand more than a palliative short-circuiting operation for relief

The operative procedures heretofore employed in this group of patients are numerous, gastroenterostomy was long the most popular (Table 3)

Table 3 *Type of Operation in the 224 Patients with Duodenal Ulcer Who Were Operated on Because of Intractable Pain or Massive Bleeding*

YEARS	TYPE OF OPERATION		
	POSTERIOR GASTROENTEROSTOMY	RESECT- TION	OTHER OPERATIONS
1922 1926	87	6	14
1927 1931	37	8	6
1932 1936	20	39	7

Stomal ulcer with its attendant high mortality has occurred so frequently that this operation must be considered entirely unsatisfactory Pyloroplasty has not been employed in many patients in this series, but where it has been, only temporary relief has often been obtained Pylorotomy fails to remove much of the acid-bearing portion of the stomach, and it too has proved unsatisfactory The only procedure that we have found gives relief to a large percentage of these patients is subtotal gastrectomy in which approximately three fifths of the stomach is removed This is in accordance with the conclusions of many other surgeons, including Finsterer,<sup>5</sup> Berg,<sup>3</sup> Lewisohn,<sup>9</sup> Ogilvie,<sup>10</sup> Marshall and Kiefer<sup>11</sup> and Graham<sup>12</sup> If it is impossible because of technical difficulties to resect the stomach, Finsterer's "resection for exclusion" may be employed, this is often required in deeply penetrating ulcers of the posterior wall

The details of subtotal gastrectomy vary considerably with different surgeons We believe

that this variation is not of great moment. While an adequate follow-up study of such cases cannot be obtained for many years after operation, we know that the patients treated in this manner have furnished exceedingly satisfactory end results. Subtotal gastrectomy following failure of more conservative operations has been required so frequently that we now carry it out as the primary pro-

cedure, and is occasionally required by an episode of massive bleeding. Thorough medical treatment is indicated in all other cases. Patients who develop cicatricial obstruction do well with gastroenterostomy. Those who develop ulcers which are intractable to medical care or have been associated with massive hemorrhage should receive subtotal gastrectomy.

Table 4 *Fatalities in 67 Private Patients Who Had Gastric Resections Performed for Peptic Ulcer (exclusive of those operated on late for massive hemorrhage)*

LOCATION OF ULCER	NO OF CASES	DEATHS
Duodenal ulcer	50	2
Gastric ulcer	10	1
Gastrojejunal ulcer and gastrojejunal fistulas	7	0

cedure in a great majority of cases. When it is properly performed on patients in the best possible physical condition, the operative mortality is extremely low (Table 4).

#### SUMMARY

The treatment of peptic ulcer has changed markedly in the last twenty years. Prompt surgery is demanded in patients who develop acute perfora-

## SYPHILITIC HEPATITIS WITH JAUNDICE\*

### Report of a Case

LEROY E. PARKINS, MD†

BOSTON

**S**YPHILITIC hepatitis with jaundice is an uncommon complication of luetic infections. It occurs in about 1 per cent of cases of early syphilis, and is usually of mild degree. In the secondary stage it is extremely rare but moderately severe. In the tertiary stage it occurs seldom, being reported by McCrae 46 times in 3300 autopsies at the Johns Hopkins Hospital. Thompson has stated that the liver is probably involved in all constitutional syphilis.

Painless afebrile jaundice in a patient with a positive blood test for syphilis presents a clinical problem that is not easy to evaluate. In essence, one must give thought to the various disease entities which may cause this type of jaundice in order to determine whether one or more diseases are present. In making a final diagnosis the past history, present illness, physical examination and all relevant tests must be considered together, no single clinical or laboratory finding is pathogno-

monic of the cause of jaundice. The question of choice between medical and surgical treatment is often a serious one. Even though the x-ray report of a cholecystogram in such a case is "pathologic gall bladder," this does not necessarily indicate that surgery is the proper treatment.

Most physicians are familiar with the modern accepted methods of anti-syphilitic therapy. To treat a patient who has syphilitic jaundice with arsenic requires a reasonable understanding of pathology and clinical medicine, because, as is well known, this alone may cause jaundice. However, fire sometimes has to be fought with fire, and such a result is no reflection on this method of treatment. All such treatment carries a risk which is relatively very slight, and is accepted by both physician and patient as being far less than that of omitting it.

Most textbooks and articles advise against such treatment. Thompson, Power and Murphy, Osler and McCrae, and others state without qualification that arsphenamine should not be used in the treatment of late syphilitic hepatitis with jaundice.

Presented at the twenty-fifth anniversary of the Peter Bent Brigham Hospital on May 6, 1938.

†Staff member, New England Deaconess Hospital.

Stokes, Wile, O'Leary and a few others assert that the contraindication is relative and not absolute. All authorities agree that potassium iodide should be tried first, but most of them recommend that mercury or bismuth be given next, before trying arsenicals. However, arsenic can be used successfully in the treatment of this type of jaundice, as has been reported by O'Leary, Stokes, Wile, and others, and is demonstrated by the following case

#### CASE REPORT

The patient, a 50-year-old, unmarried laboratory technician, was first seen in February, 1935. He complained of afebrile, painless jaundice of 5 weeks' duration. The past history was significant in that he had had rheumatism 15 years previously, the attack began with a sudden onset of sharp pain in the right heel and there were pains in various joints. The patient was in bed for 9 weeks, since then he had had mild rheumatic pains, especially during cold, damp weather, otherwise his general health had been good. He was referred to the New England Deaconess Hospital for study.

The present illness began 6 weeks before admission, when the patient had a moderate 'soreness in the bones', this increased and soon became constant, day and night. At the end of 1 week he quit his work because of loss of strength, after resting at home for 2 weeks he stayed in bed because several joints had become swollen and very painful. Five weeks later his appetite became poor and his strength was quickly depleted on slight exertion. At this time he noticed that his urine was dark. The following day he became jaundiced. He had had no abdominal pain and no complaints which were referable to the gastrointestinal tract. He had lost 10 pounds since the onset of his illness, whereas there had been no previous loss of weight. He had received no medication except aspirin and an alkaline powder, these gave no relief.

Physical examination showed universal deep jaundice and inability to sit up without aid on account of painful joints, practically all the joints were tender, and there was moderate swelling of the knees and wrists. The lungs showed rales at the right base, but were otherwise normal. The heart sounds were regular, the rate was 80 and there were no murmurs. The blood pressure was 120/80. The abdomen showed no tenderness, masses or spasm; the liver was not palpable. The pupils and other reflexes were normal. The other findings were not remarkable.

X-ray photographs were taken of the spine, joints of the extremities, chest and gastrointestinal tract, and intravenous cholangiograms were made. The films revealed a pathologic gall bladder and periosteal proliferation along the internal and posterior aspects of the right ulna, other wise they were negative.

Laboratory tests showed normal red-cell and white-cell counts, an icteric index of 35 and a blood bilirubin content of 2.1 mg per cent. Blood Wassermann, Hinton and Kahn reactions were positive on repeated tests. The spinal fluid contained 2 cells per cubic millimeter, the Wassermann reaction was doubtful on the first test and possibly positive on the second. The stools were negative for bile. The gastric contents were negative.

It was apparent that the patient had syphilis and possibly gall-bladder disease. At first it was not clear how much and what kind of treatment he should receive. He was given potassium iodide at once. A surgical consulta-

tion was requested, and the patient was seen by Dr. Leland S. McKittrick and by Dr. Elliott C. Cutler. They agreed that in view of all the findings surgery was not indicated. Anti-syphilitic medication was continued, this consisted of potassium iodide and protiodide of mercury given orally, the latter being alternated each week with quinine iodobismuth given intramuscularly.

After 4 weeks in the hospital the patient's condition gradually became worse. At this time he had a severe chill and the temperature fell to 96°F. He developed a diffuse bronchitis, heard over the left chest, and complained of severe pain in both sides of the back, the latter being caused by bilateral pleurisy. There was also severe sub-sternal discomfort, and angina-like pain over the precordia. The blood pressure at this time varied from 75/65 to 110/80, the heart sounds were regular and of fairly good quality. The patient developed auricular fibrillation, which subsided within 48 hours following the use of large doses of morphine and complete digitalization. During the 5th week the patient was no better, the mercury and bismuth were omitted at this time. It seemed reasonable to try arsenic, and 0.1 gm. of neoarsphenamine was therefore administered intravenously, no ill effects were noted. Three days later 0.2 gm. of the same drug was given, after which improvement began. Four days later 0.25 gm. was given. The dosage was gradually increased every 4 days to a maximum of 0.45 gm. From this time on, treatments were given at weekly intervals.

From the 6th to the 10th week the general condition improved. The rales in the lungs gradually subsided and the jaundice disappeared, the patient's appetite returned and his strength increased. In the first part of the 3rd month there was a transient recurrence of auricular fibrillation and edema of the feet. The blood pressure gradually returned to a normal level of 130/80, and the heart continued regular, 0.1 gm. of digitalis was given daily. Ten weeks after admission the patient was able to sit in a chair and walk a little, and was discharged to his home.

During the last 3 years potassium iodide has been given continuously, as well as fifty-six doses of intravenous and intramuscular medication consisting of neoarsphenamine, Mapharsen and quinine iodobismuth, between these doses protiodide of mercury has been given orally. A few months after leaving the hospital the patient developed hypertension, which has persisted to the date of writing at levels of 160/80 to 180/110. He has taken digitalis 0.1 gm. each day. Cardiac decompensation has not recurred. The blood Hinton reaction continued positive during the 1st year, was negative for a short time in the 2nd year and is positive at the present time, although the patient feels very well and presents no special symptoms.

#### CONCLUSION

The experience of others, together with the results in this case, demonstrates that some patients having syphilitic hepatitis with jaundice can be successfully treated with arsenicals. However, no general rule can be formulated as to which cases may be so treated.

through the suprapubic wound, the drain in the prevesical space caught on the bag and was pulled out with it. The patient's general condition was excellent, but although the suprapubic wound quickly became free of urine it was slow in clearing up and healing. Eventually, however, it healed completely. Two months later the patient began to complain of pain and swelling under the lower end of the suprapubic wound. A fluctuant bulge was opened, a quantity of thick pus was evacuated and a drain was put down in the septic prevesical space. Eventually the wound healed permanently.

In both the cases reported it is evident that the prevesical space became infected at operation, was insufficiently drained and became walled off. After

the infection had smouldered there for some weeks an abscess formed, and extended upward along the path of least resistance to the suprapubic region.

The lesson to be learned from these cases is that the prevesical drain inserted after a suprapubic operation on the bladder should not be removed prematurely or all at one time. Its withdrawal should not be started until five or six days have elapsed and the temperature has returned to normal, and the drain should then be shortened a little at a time.

352 Marlborough Street.

## REPORT ON MEDICAL PROGRESS

### STREPTOCOCCAL DISEASE\*

CHESTER S. KEEFER, M.D.†

BOSTON

THERE is no denying the fact that hemolytic streptococcal infections are among the commonest of acute infections and cause, in one way or another, a high percentage of the ill-

per cent of all the respiratory diseases. This does not include the cases of acute rheumatic fever or acute nephritis which are initiated by an infection of this type.

Table 1 *Hemolytic Streptococcal Groups*

GROUP	DISEASE	OTHER SOURCES
A	Human infections. Scarlet fever Puerperal sepsis Rheumatic fever activity Streptococcal pneumonia	Human nasopharynx and hands Cow's milk
B	Bovine mastitis due to <i>Streptococcus agalactiae</i> Human infections (rare) Arthritis Puerperal sepsis	Human throat and vagina
C	Equine strangles and endometritis Bovine mastitis Guinea pig adenitis Human infections (rare) Erysipelas	Human throat, vagina and skin
D	No human infections (?) Endocarditis (?)	Human bowel and vagina Cheese
E	No human infections	Cow's milk
F	No human infections (?) Glomerulonephritis (?)	Human throat and feces
G	No human infections (?) Canine infections	Human throat and vagina Monkey's throat
H	No human infections	Human throat and feces
I	No human infections	Human throat

ness in any community. It has been ascertained by the United States Public Health Service in a survey of the respiratory infections that hemolytic streptococcal infections are responsible for at least 5 per cent of the measurable illness and about 20

The normal habitat of the hemolytic streptococcus is in the lymphadenoid tissue of the throat. It does not grow freely on the surface of the mucous membranes but is found in the crypts of the tonsils and in the lymphoid tissue itself. About 30 or 40 per cent of normal individuals carry hemolytic streptococci in their throats at some time during the course of the different seasons of the year, the incidence being highest in the winter and early spring months. The presence of hemolytic streptococci in the human throat may be a transitory phenomenon, or they may be found over long periods of time without causing disease. Carriers are commoner in individuals who are in contact with patients with acute streptococcal infection of the throat, and such contacts are especially liable to become carriers if they have a common cold. Moreover, those who are carriers can spread organisms much easier when they have a cold. For these reasons, anyone with a cold should avoid individuals who have active streptococcal disease, and a carrier with a cold should be careful so that he does not spread infection to other individuals.

In any study of hemolytic streptococcal infection, one will find the following groups: (1) transient carriers, (2) permanent carriers, (3) patients with sub-clinical infection, and (4) patients with clinical infection. To be of any significance it must be determined that the streptococci a carrier harbors in his throat belong to Group A.

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard Medical School.

### SEROLOGICAL GROUPS AND TYPES OF HEMOLYTIC STREPTOCOCCI

Hemolytic streptococci have been divided and classified according to serological methods into nine groups<sup>1</sup> These, together with the diseases with which they are associated and with their sources, are summarized in Table 1

In general it can be said that in so far as man is concerned the vast majority of all infections are due to Group A This group, in turn, has been divided into twenty-six serological types, but since there has been very little study of such types in the United States, the percentage distribution of various types cannot be stated at the present time It is true, however, that evidence is lacking to show that the various diseases caused by hemolytic streptococci are produced by any single spe-

Table 2 *Structure of Hemolytic Streptococcus Group A*

COMPONENTS	CAPABLE OF PRODUCING ANTIGENIC RESPONSE	REMARKS
Whole organism	Yes	
M substance (protein)	No (haptene)	Type specific
C substance (carbohydrate)	No (haptene)	Group specific

Hemolysin	Yes	
Fibrinolysin	No	
Leucocidin	?	

cific type For example, Griffith<sup>2</sup> has isolated twenty-three specific types from cases of scarlet fever and of sore throat This is a subject that requires further study and investigation

### THE ANTIGENIC STRUCTURE OF HEMOLYTIC STREPTOCOCCI

The antigenic structure of human, virulent, Group A hemolytic streptococci is exceedingly complex, and our information concerning it very incomplete. However, a number of various constituents have been isolated and studied They are summarized in Table 2

### IMMUNITY TO HEMOLYTIC STREPTOCOCCI

So far as is known, hemolytic streptococci are destroyed in the body by means of intracellular digestion This is greatly facilitated by the presence of specific antibody and complement, which favors and accelerates phagocytosis There are also good grounds for believing that the macrophage and histiocyte are of greater importance in the destruction of the hemolytic streptococcus than the polymorphonuclear cells Aside from the immune mechanism which actually destroys the organism, there are other immune bodies that

develop during the course of disease These immune substances neutralize substances produced by streptococci, such as erythrogenic toxin, hemolysin and fibrinolysin, which cause deleterious effects in the body These antibodies limit the damage done to cells and aid in the localization and fixation of organisms in the tissues

### THE TREATMENT OF HEMOLYTIC STREPTOCOCCAL INFECTIONS

Within the last few years there have been a number of advances in the treatment of various hemolytic streptococcal infections The most important is the use of sulfanilamide Other methods of treatment, such as immune transfusion, antitoxic treatment and the use of streptococcal filtrates in the treatment of recurrent erysipelas, merit consideration

*Sulfanilamide* There is no longer any doubt that sulfanilamide is the best chemotherapeutic agent so far developed for the treatment of streptococcal infections In a word, it can be said that this drug has a bacteriostatic (growth-limiting) effect on all strains of human virulent hemolytic streptococci, and for some strains there is evidence that it actually has a bactericidal (killing) effect on small numbers of organisms It is most effective when antibody is present in the circulating blood, and it appears that the main function of the drug is to slow up the growth of organisms and keep the infection from progressing too rapidly until the normal defense mechanism of the body develops to the stage where there is a positive balance of antibody In other words, recovery from streptococcal infection following sulfanilamide therapy appears to be due to at least two conditions first, it is necessary to subject the organisms to a concentration of the chemical that produces maximal bacteriostasis, and, secondly, the body must retain or acquire the power to rid itself of the viable organisms that are producing the disease In order to produce maximal bacteriostasis it is necessary to give sufficient amounts of the drug so that the concentration in the blood is at least 10 mg per 100 cc Antibody is often provided by means of immune-blood transfusions

The most striking results from sulfanilamide treatment have been obtained in hemolytic streptococcal meningitis, bacteremia, puerperal sepsis, cellulitis, erysipelas, chronic empyema, osteomyelitis and chronic leg ulcer Less impressive results are reported in scarlet fever and acute tonsillitis, and there is insufficient information available concerning its value in hemolytic streptococcal pneumonia There is some suggestive evidence that its use reduces the number of cases

of otitis media and mastoiditis following tonsillitis and scarlet fever, but on this more information is necessary before a decision can be reached. In any event, there are good grounds for using this drug in all cases of hemolytic streptococcal infections.

*Immune-Blood Transfusion* Several years ago, Lyons<sup>3</sup> recommended the more frequent use or immune-blood transfusions in the treatment of streptococcal infections, especially in cases with bacteremia. The purpose of this method of treatment is to provide antibody which will aid in clearing the blood of organisms and in promoting the localization of the infection. In order that the proper donor may be selected it is necessary to establish that the donor's blood is compatible and that his blood plasma contains antibody which promotes phagocytosis of the patient's organisms. This method has the disadvantage that it requires a trained person to carry out the phagocytosis test, furthermore, in most cases it is necessary to examine a number of donors before a suitable one is found. Nevertheless, it is the best method that is available at present for supplying specific antibody to patients with hemolytic streptococcal infections.

*Antitoxic Therapy* Streptococcus antitoxin is capable of neutralizing the erythrogenic and hemolytic toxins of the organism. In some diseases, such as scarlet fever, the erythrogenic toxin is responsible for the eruption and many of the symptoms and signs of intoxication. For this reason, the use of large amounts of antitoxin early in the course of the disease is often followed by the disappearance of the rash, a sharp drop in the temperature and the amelioration of many of the signs of intoxication. Blake<sup>4</sup> has recently stressed the importance of early treatment with antitoxin in adequate doses—20,000 to 40,000 units, depending on the severity of the case. When this is carried out in cases of scarlet fever, the duration of the disease is shortened, and the course of the disease changed. In view of the frequency of serum sickness, antitoxin should probably be reserved for severe cases of scarlet fever. Antitoxin in erysipelas, puerperal sepsis and other infections has been employed with varying degrees of success. There is no doubt, however, that many of the symptoms of these diseases may be relieved. The antitoxic serum is not curative and one should not expect it to be so, since the effects of the toxin are only a part of the disease process. Nevertheless toxic symptoms add to the patient's difficulties and can be neutralized by the antitoxin, so that the latter should be used in patients with severe signs of intoxication.

*The Treatment of Recurrent Erysipelas* One

of the outstanding features of erysipelas is its tendency to recur in the same individual. The usual course of events is to observe two attacks coming on within several weeks of one another, but there are numerous instances in which patients may have frequent attacks occurring over a period of months or years. These recurrent attacks may involve the face or the extremities.

While the mechanism for the production of these recurrent attacks is not absolutely clear, there is suggestive evidence that, as a result of a previous hemolytic streptococcal infection which has caused erysipelas, the skin of the involved area becomes sensitized and highly susceptible to the products of the hemolytic streptococcus, so that the presence of hemolytic streptococci in the tissues in small numbers can cause a very acute reaction. In recurrent erysipelas of the face, one can frequently find hemolytic streptococci or staphylococci in the nasal discharge, and often there is evidence of a chronic nasal sinusitis due to these organisms (Stevens<sup>5</sup>). In the case of recurrent erysipelas of the legs, it has been demonstrated by Amoss<sup>6</sup> that hemolytic streptococci invade the tissues from small breaks in the skin that are so often present in epidermophytosis.

It is also known that one does not need hemolytic streptococci in the area of acute inflammation to produce an acute attack of erysipelas, since a recurrent attack can be produced in susceptible individuals by injecting toxic filtrates of hemolytic streptococci into the subcutaneous tissues. For example, if an individual is subject to recurrent erysipelas of the face, an attack can often be produced by injecting a small amount of sterile toxic filtrate into the subcutaneous tissues of the arm. This indicates that the toxic products of the hemolytic streptococci or staphylococci are capable of producing the reaction in susceptible areas of the skin. Naturally in the course of the recurrent attacks there must be a focus of infection in some area from which toxic products are absorbed.

The treatment of recurrent attacks of erysipelas, then, consists of (1) elimination of the foci of infection, such as chronic nasal sinusitis, and the proper care of the feet, and (2) repeated injections of the patient with the products of the hemolytic streptococcus or staphylococcus. To obtain satisfactory results it is necessary to use both of these methods of treatment.

The treatment is carried out as follows.<sup>5</sup> Hemolytic streptococci and staphylococci are obtained by culturing the nasal discharge. These organisms should be grown in proteose-peptone broth in an atmosphere of carbon dioxide for several days. The culture should then be passed through

a Berkefeld filter, and the filtrate tested for sterility. Subcutaneous injections with the filtrate should be made twice a week, starting with 0.1 cc of a 1:200 dilution and increasing the amount until 1 or 2 cc of undiluted filtrate can be tolerated. During these injections a critical dose is often reached, usually between 0.1 and 0.2 cc of undiluted filtrate, which is followed by swelling of the face or other affected parts. If this amount is reduced the reaction does not recur, and one can then increase the dose gradually so that finally 1 or 2 cc of undiluted filtrate is tolerated. If the patient can tolerate this amount of undiluted filtrate and if the focus of infection has been removed, the recurrent attacks usually cease. This form of treatment is most satisfactory in a high percentage of cases of recurrent erysipelas or so-called infectious edema of the face.

\* \* \*

Unfortunately there is no effective method of treatment of subacute bacterial endocarditis due to *Streptococcus viridans*. There are isolated cases in which the blood has been temporarily sterilized following the use of sulfanilamide, and rare cases have been observed in which long remissions and the complete absence of symptoms for as long as eighteen months have occurred follow-

ing the use of the drug. The chief difficulty in the effective treatment of subacute bacterial endocarditis is attacking and destroying the organisms at their source in the heart valves. If one were able to destroy the vegetations so that the organisms would no longer be protected from the action of specific antibodies and leukocytes, the question of recovery would appear to be relatively easy. Very often the blood is sterilized, but the organisms continue to grow in the vegetations and to leave the focus from time to time so that the signs of active infection progress, regardless of a high antibody titer in the blood. This disease remains a challenge to medical investigation, and to effect a cure it appears likely that some method must be devised that destroys the vegetations on the heart valves.

## CASE 25031

## PRESENTATION OF CASE

*First Admission* A fifty-year-old, married Greek laborer was admitted because of a discharging sinus over the dorsal spine.

Eight months before entry a small painless swelling appeared on his back between the shoulders in the midline, which he thought was a boil. It remained unchanged after poulticing, and he consulted a physician, who said that it was a cyst and advised removal. After removal the wound healed perfectly within ten days. A few weeks later a second swelling appeared lower down opposite the angle of the scapula and to the right of the midline. This time at an outside hospital a 15 cm. operative incision was made which healed well except for a small sinus opposite the ninth thoracic vertebra. The sinus remained open up to the time of entry and on two or three occasions discharged a small piece of bone. He had felt well and had no other complaints.

For many years he had been a night watchman and later an elevator operator. He was born in Greece but had been in Massachusetts for thirty-two years, although he had returned to the "old country" three times during this period. Since childhood he had had "lumps" in his neck.

Physical examination showed a well-developed and nourished man in no distress. There was a small, healed, non-tender scar on the back of the neck in the midline. At the top of the scar there was a small 5 mm. nodule. Just to the left of the scar, a larger nodule was noted, which was hard, non-tender and freely movable. A 15 cm. scar was present to the right of the midline, extending from the thoracic to the upper lumbar region. In the center of the scar was a very small, non-tender draining sinus. Except for a few carious lower teeth, he was edentulous. Examination of the neck showed a mass 3 by 3 cm. just below the angle of the left jaw, medial to the sternomastoid; it was firm, non-fluctuant, freely movable and non-tender. Examination of the chest was negative. The blood pressure was 138 systolic, 80 diastolic. The abdomen showed bilateral inguinal hernias.

The temperature was 98.8°F, the pulse 100, the respirations 28.

The urine examination was negative. The blood showed a red-cell count of 3,600,000 with 65 per cent hemoglobin, and a white-cell count of 7000 with 65 per cent polymorphonuclears, 28 per cent lymphocytes, 4 per cent mononuclears and 3 per cent eosinophils. A blood Wassermann test was negative.

X-ray films of the spine showed a rounded area of diminished density in the right transverse process of the fifth dorsal vertebra and slight irregularity in the adjoining portion of the rib. The medial portion of the sixth rib in the region of the tuberosity showed increased density and was somewhat irregular in outline. Lipiodol injected into the draining sinus communicated with the area of destruction in the rib. Chest films showed old calcified tuberculosis at each apex.

On the eleventh hospital day he was discharged to his local physician with a diagnosis of chronic osteomyelitis.

*Second Admission* (four years later) Five months after discharge the patient returned for examination, at which time the sinus had healed. There was good mobility of the spine, and no pain. He was well until three weeks before readmission when the pain recurred in the midline of his back at the site of the old operation. It was aggravated by motion. Four days later he noted a swelling, which became very tender, to the right of the midline on his upper back. He had had no chills or increased perspiration.

Physical examination showed a cervicodorsal kyphosis. There was a tender fluctuant area on the back 3 cm. in width to the right of the midline, extending from the first to the fifth dorsal vertebra. Two small, round, hard nodules were present on the back of the neck just to the left of the midline opposite the fourth and seventh cervical vertebrae.

Examination of the urine was negative. The blood showed a red-cell count of 4,200,000 with 70 per cent hemoglobin, and a white-cell count of 8900.

X-ray films showed a definite variation from normal in the third, fourth and fifth dorsal vertebrae. The joint spaces were hazy and narrow. The heads and necks of the fifth, sixth and seventh ribs showed marked irregularity and contained areas of bone formation and destruction.

On the day of admission an incision was made into the fluctuant area, and 180 cc. of thick, yellow pus was evacuated. The abscess cavity seemed to run upward beneath the muscles over the right shoulder. On the thirteenth hospital day the

wound showed good granulation and the patient was discharged

*Third Admission* (seven years later) One year before, he entered the surgical clinic for removal of a "wen" on the right side of his back, which had been present for six years

He had enjoyed excellent general health until one month prior to his final entry when his urinary stream decreased to a dribble. At the same time constipation increased. One week later he noted numbness and weakness in his legs. He was able to obtain relief at first by vigorous exercise, but this soon became impossible. One week before entry he was unable to stand. At this time he also noted a large mass in the suprapubic region and had a desire to urinate. When he was assisted to his feet he became incontinent to the extent of dribbling. Since then he had not been able to void.

Physical examination showed a depressed scar over the two upper dorsal vertebrae 3 to 4 cm in depth, in addition to his other scars. Three small movable nodules were present below some matted nodules in the right posterior triangle of the neck. Chest and abdominal examinations were negative except for palpation of the liver edge 2 cm below the costal margin. The edge was sharp and non-tender. Rectal examination revealed a lax sphincter. The prostate was small, firm and non-tender. The spinous processes of the seventh cervical and first dorsal vertebrae were absent. There was decreased response to all forms of sensory stimuli below the level of the fourth dorsal nerve anteriorly and posteriorly. A spastic paraplegia was present, with the left leg weaker than the right. The knee and ankle jerks were markedly hyperactive, and there was a positive Babinski sign on both sides.

The temperature was 99°F, the pulse 80, the respirations 20.

Examination of the urine showed many clumps of white cells and a rare hyaline cast. No Bence-Jones protein was found. The blood showed a red-cell count of 4,190,000 with 77 per cent hemoglobin, and a white-cell count of 9350 with 70 per cent polymorphonuclears, 24 per cent lymphocytes, 1 per cent mononuclears, 1 per cent eosinophils and 4 per cent basophils. The serum non-protein nitrogen was 29 mg per cent, the protein 8.2 gm. A blood Hinton test was negative. A lumbar puncture showed an initial pressure of 130 mm of water, but combined jugular pressure gave no response. Abdominal pressure caused a rise to 350 mm. The spinal fluid was clear but xanthochromic. It contained 1 lymphocyte per cubic millimeter. The total protein was 378 mg

per cent. The goldsol was 0444333110, the Wassermann negative.

X-ray films of the chest showed mottled areas of dullness in both apical lung fields, especially on the right, with multiple areas of calcification. There were also areas of calcification in both middle lung fields and the soft tissues of the neck. The dorsal spine showed hypertrophic changes. There was no evidence of metastatic cancer. There was partial destruction of the right side of the third dorsal vertebra, with absence of the pedicle in this area. The adjacent portion of the third rib was destroyed. There were cyst-like areas in the medial portions of the second, sixth and seventh ribs and in the fifth, sixth and seventh transverse processes on the right. No deformity of the vertebrae was present which could explain a paraplegia. There was evidence of Paget's disease of the ilium and sacrum on the left side. The skull was negative.

During the first ten days in the hospital the compression damage to the cord gradually increased, and on the tenth day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. ALFRED O. LUDWIG. Apparently there had been some change in the x-ray of the spine at the time of his second entry, as it was beginning to show more involvement of the ribs. May we see the films?

DR. AUBREY O. HAMPTON. The x-ray films taken at the time of the first admission are not here. The films that we have show obvious disease in the spine and ribs. The process has extensively involved at least half the dorsal vertebrae, and the ribs adjacent to these vertebrae are surrounded by a fair-sized soft-tissue mass simulating an abscess. The abscess, if it is one, is surprisingly small for so much disease in the vertebra if it were due, let us say, to tuberculosis.

DR. LUDWIG. Is it not unusual for tuberculosis to cause this much destruction without collapse of the vertebrae?

DR. HAMPTON. Yes, and the joint spaces of these vertebrae are narrowed but not moth-eaten and irregular as you would expect. There may be destruction in the third dorsal vertebra, but since we cannot see it in the lateral view, we have no proof of it.

DR. LUDWIG. How about other types of infection, osteomyelitis of the spine, for instance?

DR. HAMPTON. I do not understand this appearance in the rib. It looks like an expansile lesion on first glance, but I do not believe the rib is actually enlarged. That is the cystic area described, a very curious thing.

DR. LUDWIG The pictures do not suggest myeloma?

DR. HAMPTON No, I do not believe it is a tumor. It is probably an infection. The only thing that makes me think of tuberculosis is the calcification in the region, some of it, however, may be in the lung and some in the supraclavicular glands, instead of around the spine.

DR. LUDWIG Do these findings suggest an actinomycotic infection of the bones of the spine? From what I am able to gather this disease does destroy ribs and transverse processes.

DR. HAMPTON I think that actinomycosis would be more liable to cause complete destruction in the primary area, with gradual spread instead of spotty destruction such as we have here. The infection in this case skips two ribs and then shows destruction of one at each end of the areas. It is a very unusual picture by x-ray, and I do not know what it is.

DR. LUDWIG Is there anything to suggest an actinomycotic infection?

DR. HAMPTON No.

DR. TRACY B. MALLORY How about infection caused by the typhoid bacillus?

DR. HAMPTON Any infection could produce this picture.

DR. LUDWIG I thought I was going to get more help from the x-ray than I did.

To go back to the beginning of this case, it seems to me the first statement we have that might be of some importance is that this man of fifty had had lumps in his neck since childhood. I am inclined to interpret them as being a manifestation of cervical tuberculous adenopathy which existed during childhood but which was inactive at the time of hospitalization. He apparently had pulmonary tuberculosis at some time, with healing and calcification in the region of the old lesion. His recent trouble dates back to eight months before the first entry, then the process went on for eleven years before his last admission here. The most outstanding symptoms were tenderness and constant stiffness in the upper part of the spine, with rather marked pain, nodular swelling and sinus and eventually abscess formation. On the second admission, a very large abscess was found, which contained 180 cc of pus. Interestingly enough there were few constitutional signs, very little temperature or pulse increase, not very much increase in the white count, very moderate anemia and little weight loss. Then we come to his last admission and another new neurologic symptom. As to the diagnosis of the underlying disease one has to think of tuberculosis, but according to Dr. Hampton's interpretation and from what I know of the x-ray findings in tuberculosis of the spine,

these are certainly not the ordinary findings of that condition. From what I am able to discover one sees such changes in actinomycosis, and this disease can produce extensive destruction of the spine without collapse of the vertebrae. However, actinomycosis and blastomycosis are diseases of relatively short duration, — a year or two at the most, — and this has gone on for eleven years.

His final episode is obviously due to compression of his cord, but there seems to be no evidence from the x-ray that such compression is due to a collapsed vertebra.

DR. HAMPTON I should have mentioned the possibility that he has a secondary infection superimposed on a tuberculous abscess.

DR. LUDWIG I think it is probably true that when draining sinuses appear in such a case they are almost invariably due to secondary infection. There is one note in the history of a sequestrum's being discharged from a sinus. So far as actinomycosis or blastomycosis is concerned sequestrums are usually absent because large pieces of bone become necrotic. That also holds true of tuberculosis. The spinal-fluid findings, including the gold-sol curve, are characteristic of block, and I believe his neurologic findings are due to extradural abscess formation, with compression of the cord. The serum protein of 8.2 per cent is interesting. Except dehydration I know of only one condition that can cause such a deviation, namely multiple myelomas. I do not know whether it is increased in other types of bone tumors or in amyloid disease, which this man might well have had. He had a liver which seemed to have increased in size at the last entry, when it was found to be 2 cm below the costal margin. It could not be felt before — at least it was not mentioned. He had none of the other findings of amyloid disease, neither the kidney changes usually giving the picture of nephrosis nor an enlarged spleen. There was only a single determination of the protein so that I am not inclined to place too much importance on that finding. Furthermore, the x-ray findings are not those of multiple myelomas. In this disease there is usually far more anemia than he had and the bone lesions are more often multiple, rather than localized to one small area. Apparently they found Paget's disease in the pelvis on the right side, but I do not see how that could have had anything to do with the situation.

I shall stick to a diagnosis of an infectious process involving the spine, that is, an osteomyelitis, which I do not believe was due to tuberculosis. I do not know what the infectious agent was. Had it been actinomycosis the patient would not have lived so long as he did, and the typical sulfur

granules should have been found. I think the neurologic symptoms of compression of the cord were due to extradural abscess formation, secondary to the infection of the bones of the spine. He had Paget's disease, which I do not believe plays any essential part in the symptomatology.

DR MALLORY: Are there any suggestions?

DR WILLIAM J MIXTER: There is a chance that the patient may have had a perfectly normal space for fluid to pass up and down around the spinal cord without compression of the cord and that the symptoms were the result of a transverse myelitis due to infection.

A PHYSICIAN: Could the spinal-fluid picture be produced by venous thrombosis?

DR MIXTER: Yes.

A PHYSICIAN: With tremendous increase of blood supply and no place for it to go?

DR MIXTER: I think so, more probably thrombosis, either arterial or venous, without cord compression. I should guess that it was chronic non-tuberculous osteomyelitis, or a secondary process to an original tuberculous focus.

DR JAMES C WHITE: As soon as we came down to the posterior surface of the lamina the diagnosis became apparent. Numerous cysts of varied size had worked their way out between the laminae and lay between the bone and muscles. We had thought of the possibility of echinococcus disease, because this man was a Greek, but had not pursued the suggestion. We had also asked about the "wen" that had been removed. He said it was a wen, but in retrospect it is likely that it was an echinococcus cyst. As we cut down through the bone, it was soft and there were a great many cysts between the bone and the dura. There was definite compression of the cord. Furthermore, there was erosion in the pedicles which opened into a large cavity in the extrapleural tissues on the right side. Just how big this area was, I do not know.

#### CLINICAL DIAGNOSIS

Inflammatory compression of the spinal cord

#### DR LUDWIG'S DIAGNOSES

Osteomyelitis of vertebrae and ribs, with paravertebral abscess and sinus formation

Extradural abscess

Compression of the spinal cord

Paget's disease

#### ANATOMICAL DIAGNOSIS

Echinococcus cysts involving vertebrae, extradural space and extrapleural tissues

#### PATHOLOGICAL DISCUSSION

DR MALLORY: I imagine that this was the only Greek who was ever in the hospital on whom an echinococcus complement fixation test was not done. Of course it should have been done. The cyst was very typical and contained daughter cysts and numerous hooklets. There is no question that some of the cysts were secondarily infected, and probably the original draining sinus developed in this way.

DR LUDWIG: There is no evidence that there was cystic disease anywhere else? How about the lungs?

DR MALLORY: I think in retrospect the lungs were probably involved.

DR HAMPTON: I do not believe I have ever seen a cyst in the bone like that.

DR MALLORY: We know very little about such lesions. Before seeing this case, we did not appreciate that bone could be involved, but in looking the matter up in Kaufmann's textbook, we discovered that involvement of the spine is not uncommon.

DR THORNTON SCOTT: Coley\* reported two cases in 1932.

DR WHITE: Dr George W. Van Gorder had a case where the hip bone was involved.

DR HAMPTON: We have seen it involving bone secondarily but not as a primary cyst in the bone.

DR MALLORY: The echinococcus test was done afterward and was positive.

#### CASE 25032

#### PRESENTATION OF CASE

A six-month-old infant boy entered the hospital for treatment of a cold, running nose and fever of thirty-eight hours' duration.

The child had been well until the morning of the day before entry, when he seemed tired and listless and for the first time in his life had a running nose. That afternoon he vomited on four occasions, bringing up lavender-colored material. A physician was called who found his temperature to be 101°F and made a diagnosis of a "cold in the chest." The child slept well that night and did not seem to be feverish. He refused his milk but drank some water. The following morning he was very drowsy, although at intervals he became fairly alert. He continued to take water but still refused milk. In the middle of the afternoon his mother gave him an enema because his bowels had not moved for twenty-four hours. A hard stool was obtained, followed immediately by a gush of bright red blood. The blood was

Coley B. L.: Echinococcus disease of bone: report of two cases involving the pelvic girdle. *J. Bone & Joint Surg.* 14:577-590, 1937.

estimated to be enough to fill a small wine glass. A physician was called and found the child's temperature to be 102°F. He said the child's neck was stiff and advised immediate hospitalization. He was brought into the Emergency Ward that evening. During his illness he had not shown difficulty in respiration and had had no twitchings, convulsions or vomiting, except as noted above.

He had been delivered normally at full term and had apparently steadily gained weight since birth. He had had no previous illnesses. He had six siblings who were living and well. One sibling had died in a "convulsion" at the age of eleven months, and one had died of 'suffocation' at the age of six weeks.

Physical examination revealed a well-developed and well-nourished, extremely sick, pale, somewhat cyanotic infant who was too ill to resist attempts at examination. There was slightly diminished resonance over the right chest, with a tendency to bronchial breathing but no rales. The heart was negative. The abdomen was very much distended, with absent peristalsis, it had a doughy consistence and was tympanitic throughout. There was no spasm, and no masses were palpable. There was a bright-red, bloody discharge from the anus, and on rectal examination the examining finger seemed to reach an indefinite mass which slipped away from it.

The temperature was 102.6°F., the pulse 160, the respirations 52.

The blood showed a white-cell count of 14,300. An x-ray film showed no evidence of disease in the chest. There was a large amount of gas in the small intestine, all the loops being slightly dilated, however, there was not marked dilatation of a single loop. In the right lower quadrant there was a beak-like deformity with narrowing at one end.

A laparotomy was performed a few hours after entry.

#### DIFFERENTIAL DIAGNOSIS

DR. LEO B. BURGIN. At the outset we may say confidently that this infant had an acute upper respiratory infection. The nasal discharge, fever and white count are typical. The vomiting may likewise be considered consistent. Infants frequently manifest the presence of infection anywhere in the body by vomiting. Can we attach any significance to the lavender vomitus? It is certainly not blood. Could this represent some foreign material that the infant ingested? Probably not. Such a color might conceivably be due to a reaction between iodine present in frequently used nose-drops (iodine, camphor and menthol)

and undigested starch in the stomach. I shall pass it by. The anorexia and drowsiness that occurred during the subsequent twenty-four hours could go very well with the respiratory infection.

At the end of this time a new symptom made its appearance—melena. In determining the source of melena, the nature of the blood as it appears on the outside—that is, whether it is clotted and whether it is pure blood or an admixture with fecal material or mucus—is important. In this instance it is reported as being bright-red blood. Can we tie this up with the respiratory infection? Parenteral diarrheas are not uncommonly seen with respiratory infections. However, we should expect loose watery stools, mucus and, in the case of enteric diarrhea or colitis, pus. This is not the case here. We shall have to look to other causes for an explanation.

Duodenal ulcers occasionally occur, particularly in young infants. Blood, when present, is usually tarry in nature and as a rule well mixed with fecal material, rarely is bright-red blood seen. The vomitus would very likely be described as coffee-grounds or frankly bloody. The peritoneal reaction that was present—distention and a doughy abdomen—and the critical appearance of the infant could suggest perforation. However, most of the findings point to a lesion considerably lower in the gastrointestinal tract.

Henoch's purpura can give bleeding of various types, particularly if the bleeding points be widely separated. In such a case, we might have a combination of tarry stools and bright-red blood. The abdominal findings could be the result of extensive intestinal hemorrhage. However, we should expect to find mention of the typical, associated, purpuric lesions of the skin. Bleeding due to blood dyscrasia of one sort or another or to hemophilia does not appear likely from the history. Congenital telangiectasia involving the gastrointestinal tract might be considered as a possibility. But this is quite rare and usually associated with microscopic bleeding occurring over a long period of time and leading to marked secondary anemia and with a familial history. There is no evidence for it here.

A bleeding rectal polyp could explain some of the findings. The suggestive mass that slips away on rectal examination might represent such a polyp. It should be accessible to proctoscopic examination and would probably be associated with tenesmus and an appreciable outpouring of mucus from the rectal mucosa. This was not the case.

We are left with the consideration of two possibilities: bleeding from a peptic ulcer in a Meckel's diverticulum and intussusception. There are a

number of features which favor either of these diagnoses. The age and sex of this patient are consistent with a diagnosis of intussusception. Usually the previous health is described as good. As in this case, an upper respiratory infection may initiate the intussusception. However, no mention is made of pain which is usually characteristic, coming in bouts as each peristaltic wave tends to push the invaginated intestine onward. On one occasion I saw an eleven-month-old, stoic Chinese infant who had other signs of intussusception but gave no history of pain. The sausage-shaped tumor of intussusception is not described here. The indefinite mass felt by rectum could conceivably be the apex of the intussusception. The doughy consistence of the abdomen, the distention and the absent peristalsis might be due to obstruction and peritoneal reaction attending early gangrene, although the elapsed time was shorter than that usually necessary for such a process to take place. Furthermore, there is no mention of the "currant-jelly" mixture of blood and mucus that is so typical of the disorder, unless we assume that the "bright-red bloody discharge" is a veiled description of such a finding. The clinical signs in the chest could easily have been due to abdominal distention. This was confirmed by subsequent x-ray examination.

We then come to a consideration of Meckel's diverticulum. The symptomatology varies according to whether there is obstruction, inflammation or ulceration, or a combination of these. Bleeding is usually associated with ulceration resulting from the acid secretions of ectopic gastric mucosa in the diverticulum. The bleeding may vary from simple streaks of blood, with or without admixture of fecal material, to frank gross hemorrhage. The bleeding is not attended with any great amount of pain. The diverticulum may be the source of an intussusception. In this event the symptoms of intussusception predominate. The other abdominal findings—doughy abdomen, distention, absent peristalsis, and so forth—may represent evidence of peritonitis due to perforation. In infants with peritonitis a doughy abdomen may be found rather than the typical board-like abdomen. However, this consistence of the abdomen might be due to

a large internal hemorrhage. The absence of pain is not of itself an objection to a diagnosis of perforation. Pain is an unreliable symptom in infancy. The x-ray report referring to a "beak-like deformity" in the right lower quadrant I do not comprehend. It does suggest something going on in an area consistent with the location of a Meckel's diverticulum, and I believe that the latter is the diagnosis. There may have been a perforation.

#### PREOPERATIVE DIAGNOSIS

Intussusception

#### DR. BURGIN'S DIAGNOSES

Acute upper respiratory infection  
Peptic ulcer of Meckel's diverticulum, possibly with perforation

#### ANATOMICAL DIAGNOSES

Primary intussusception of ileum  
Secondary intussusception of ileum into cecum

#### PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY. As is often the case, the written summary failed to give a clear impression of the clinical status of the patient. This was a desperately ill infant, and the surgeon, Dr. Robert R. Linton, who was called to see him in consultation immediately after entry noted with alarm the child's complete apathy to all modes of examination. He was evidently more impressed with the mass felt on rectal examination than was Dr. Burgin from merely reading the story, since he committed himself to a diagnosis of intussusception. The patient was prepared immediately for operation with intravenous fluid and a clvsi and taken to the operating room.

Exploration showed a double intussusception, evidently primary in the ileum, with secondary intussusception of this mass into the cecum. The secondary cecal intussusception proved readily reducible but the primary one in the ileum was not. The bowel wall showed considerable necrosis, and resection was necessary. The child failed to rally and quietly expired a few hours later. Postmortem examination contributed no further information.

**THE JOURNAL** does not hold itself responsible for statements made by any contributor.

**COMMUNICATIONS** should be addressed to the NEW ENGLAND JOURNAL OF MEDICINE, 8 Fenway Boston, Mass.

## WHAT SHALL I SUBSCRIBE?

SOME time between January 23 and February 7, every man and woman in Greater Boston will be solicited by a representative of the Community Fund Campaign—now an established enterprise in the life of our Metropolitan community. Every physician will have to make up his mind what he will pass on to the support of one hundred and fourteen agencies and federations, comprising more than one hundred and fifty hospitals, health centers and social-service organizations.

Those who have decided that they can and will give money frequently have much difficulty in arriving at a proper figure, and certainly no man can tell them individually what each should give. Thoughtful people, however, want to be intelligent givers and often welcome general information as

to some of their colleagues' standards, both as regards motives and amounts.

The charitable works of the profession as a whole and individually in any community are too well known to require comment here. Doctors by the very nature of their education and experience are socially minded. They contribute continuously of themselves. They—at least all but a few of them—believe, moreover, that they should not only give of their time and skill to the medical care of the people, but also contribute of their means to a comprehensive community program that ministers to all sorts of human needs. The great majority of physicians see the necessity of maintaining social and medical agencies as a *sine qua non* of preserving our present democratic system of life—the American system.

These men, desirous of taking their full share, are sometimes in doubt about the amount they should subscribe. To them should be said: "Determine first what can be easily afforded without sacrifice—then add an amount which entails *some* sacrifice."

A suggested basis of subscription issued by the Community Federation is a scale of giving that is graduated according to income, and from it one gathers that the standard for professional people varies from one per cent up to three per cent of yearly income. The statement, however, adds: "Giving must be adapted to individual circumstances. Some can afford to subscribe on a more liberal basis." If the doctors of Greater Boston can approach these figures, they will go well over the top of their quota, which is \$21,555, and thereby help to achieve a much needed oversubscription of the total goal of \$4,645,000.

The opportunity of making monthly or quarterly payments cannot be overemphasized. Thoughtlessly a doctor may give a solicitor a ten-dollar bill, hoping that by so doing he will rid himself of further obligation for the rest of the year. Could he be offended if he were asked to give the same amount every month or every three months during 1939?

In other words, each subscriber must answer for

himself these questions: What is my full share of support for this vast and inclusive community program? What should I give throughout the year for service that is continually rendered to the needy?

### A BASIS FOR FEE INSURANCE

THAT there is a general movement throughout the country to enable the consumers of medical service, particularly those in the low-income group, to pay their physicians' bills on an insurance basis cannot be denied. Furthermore, the scheme has been approved by organized medicine, with the proviso that all payments should be made in cash and that "agencies set up to provide such insurance should comply with state statutes and regulations to insure their soundness and financial responsibility and have the approval of the county and state medical societies under which they operate," and identical action was taken at the recent annual meeting of hospital administrators.

There remains the necessity for devising ways and means of providing reasonable forms of insurance. It is obvious that a plan which is acceptable in one state is not necessarily one best suited to another section of the country, for fee schedules and types of illness vary geographically. As a result, each state or subdivision thereof must determine the scheme best adapted to meet its particular needs.

The people of Massachusetts have had little, if any, experience with this type of insurance—with the exception of health insurance, as furnished by the old-line insurance companies. It seems reasonable to assume that an organization of the non-profit variety, under the supervision of physicians, public-health officials and hospital administrators, would be able to furnish adequate care at a lower figure than a commercial company with its overhead charges and its money-making responsibilities.

With this in mind the Associated Hospital Service Corporation is endeavoring to accumulate data in regard to professional fees that will serve to

provide a basis for the necessary charges in an insurance scheme to pay physicians' bills. A questionnaire in regard to their bills has been sent to twelve hundred physicians whose patients have had their hospital bills paid in full or in part by the Blue Cross. Already more than five hundred replies have been received. However, a much higher percentage must be obtained in order to provide figures that are representative, and all physicians who have received these questionnaires are earnestly requested to fill them out and forward them at the earliest possible moment.

### MASSACHUSETTS MEDICAL SOCIETY

A STATED meeting of the Council will be held in John Ware Hall, Boston Medical Library, 8 Fenway, Boston, on Wednesday, February 1, at 10.30 a m.

#### Business

- 1 Call to order at 10.30 a m
- 2 Presentation of record of last meeting (Published in *New England Journal of Medicine*, 219 749-762, 1938)
- 3 Reports of Auditing Committee and Treasurer
- 4 Reports of standing committees
- 5 Reports of special committees
- 6 Appointment of delegates
  - a To the House of Delegates, American Medical Association, for two years from June 1, 1939
  - b To the annual meetings of the five New England state medical societies in 1939
  - c To the Annual Congress on Medical Education and Licensure, American Medical Association, at the Palmer House, Chicago, February 13 and 14, 1939
- 7 Incidental business

ALEXANDER S. BEGG, *Secretary*

Councilors are asked to sign one of the two attendance books before the meeting. The Cotting Luncheon will be served immediately after the meeting.

SECTION OF OBSTETRICS  
AND GYNECOLOGY

## POSTPARTUM HEMORRHAGE

The case reports that have appeared in the *Journal* for the past two years have been collected from actual cases occurring in private and general hospital practice. As the different subjects were prepared it was very interesting to observe how easy it was to assemble cases on some subjects and how difficult on others. In fact, some presumably frequent conditions were relatively rare, and vice versa. For example, it was very hard to obtain reports of cases of placenta previa, but very simple to get them of cases of separated placenta. Hence, we believe that the hemorrhage in the majority of cases that bleed in the last few months of pregnancy is caused by some degree of separation of the placenta and that the occurrence of placenta previa of any sort is relatively uncommon. Placenta accreta has become an obstetrical entity solely because of expert pathological examination, it has only been in the last few years that the condition has been recognized, and cases of this sort have been difficult to accumulate. Their actual frequency can be determined only over a period of many years and is dependent on the establishment of adequate pathological departments in all our institutions in which obstetrics is practiced.

The next subject to be discussed is postpartum hemorrhage. We believe that there will be no great difficulty in obtaining cases of this sort. We shall confine the cases to those in which postpartum hemorrhage occurred at the time of labor or within the first few hours after delivery. Bleeding occurring later than this is classified as hemorrhage during the puerperium and will be taken up as a separate topic. The postpartum hemorrhage associated with ruptured uterus and placenta accreta has already been considered and will not be discussed further.

Atony of the uterus resulting in death is fortunately uncommon. Most cases of atonic uteri respond to some form of oxytocic stimulation. We have been brought up on the idea that overdistended uteri, such as those associated with hydatidiosis and twins, are prone to postpartum hemorrhage. We also connect postpartum hemorrhage with labors that are unduly long or unduly short. The cases that will appear sub-

sequently may or may not bear out these inherited inferences. Postpartum hemorrhage also follows lacerations of the cervix, perineum and vestibule. Bleeding from a laceration of the cervix is not nearly so common in this day of conservative operating as it was in the heyday of accouchement forcé. Postpartum hemorrhage is also associated with partially adherent and partially separated placentas. Illustrations of this sort we hope to find.

In practically all these cases of postpartum hemorrhage the question of transfusion arises. The necessity for obtaining a compatible donor, without too much delay, will be emphasized, and the aftercare of patients who have suffered acute loss of blood at the time of delivery will be considered.

## DEATHS

CAHILL—HARRY P. CAHILL, M.D., of 35 Crowninshield Road, Brookline, died January 15. He was in his fifty-sixth year.

Born in Worcester he attended the Worcester schools and Holy Cross College and received his degree from the Harvard Medical School in 1911. He interned at the Boston City Hospital where he eventually became chief of the Nose and Throat Service. When this country entered the War he was doing graduate research work in otology at the University of Basle in Switzerland as a Harvard Fellow. He returned here and entered the Medical Corps of the United States Army and, as a captain, served in France for ten months with the American Expeditionary Forces.

Dr. Cahill was professor of otology at the Tufts College Medical School, assistant professor of otology at the Harvard Medical School and, for many years, surgeon at the Massachusetts Eye and Ear Infirmary.

Among his affiliations were fellowships in the American Medical Association and the Massachusetts Medical Society, and memberships in the American Academy of Ophthalmology and Oto-Laryngology, the American Otological Society and the New England Otological and Laryngological Society. His widow, two sons and his mother survive him.

MARR—EDWARD L. MARR, M.D., of 17 West Wyoming Avenue, Melrose, died December 17, 1938. He was in his sixty-second year.

Born in West Southport, Maine, his family moved to Malden where he attended the local schools. In 1898 he enlisted for service in the Spanish War. He received his degree from Tufts College Medical School in 1910. Dr. Marr had practiced in Melrose for twenty-six years and was a school physician for fifteen years.

Among his affiliations were fellowships in the American Medical Association and the Massachusetts Medical Society. He was departmental surgeon for the Massachusetts department of the Spanish War Veterans.

His widow, a son, a daughter, a brother and a sister survive him.

PARKER—CHARLES C. PARKER, M.D., of 130 Gallivan Boulevard, Dorchester, died recently. He was in his forty-seventh year. Dr. Parker received his degree from Tufts College Medical School in 1918. He was a fellow of the American Medical Association and the Massachusetts Medical Society.

His widow, a daughter and two sons survive him.

**TALBOT**—**BERTELL L. TALBOT, M.D.**, of Milford, New Hampshire, died July 14, 1938. He was in his sixty-sixth year.

Dr. Talbot received his degree from the Harvard Medical School in 1896 and was a member of the American Medical Association and the Massachusetts Medical Society.

His widow survives him.

**THOMPSON**—**JOHN S. THOMPSON, M.D.**, of Antigonish, Nova Scotia, died January 8. He was in his seventy-sixth year.

Born in Antigonish, he attended St. Francis Xavier College in that town and received his degree from Georgetown University School of Medicine in 1895. He served in the navy a short time before beginning medical practice in Cambridge in 1900. Dr. Thompson retired from active practice about eight years ago.

He was a former member of the Massachusetts Medical Society.

A brother, a sister and a niece survive him.

## NEW HAMPSHIRE MEDICAL SOCIETY

### DEATH

**BLANCHARD**—**ROSCOE G. BLANCHARD, M.D.**, of Dover, New Hampshire, died on January 12, 1939, at the age of eighty-six.

He was born in West Cumberland, Maine, in 1853, graduated from Bowdoin College in 1884 and had practiced in Dover since that time.

Dr. Blanchard was a member of the local county and state medical societies and the American Medical Association. He was prominent in various Masonic bodies.

## VERMONT STATE MEDICAL SOCIETY

### VERMONT DEPARTMENT OF PUBLIC HEALTH

The following communicable diseases were reported to the office of the Department of Public Health during the month of October: chickenpox, 204, measles, 8, undulant fever, 2, scarlet fever, 19, typhoid fever, 4, whooping cough, 220, mumps, 42, lobar pneumonia, 3, German measles, 6, Vincent's infection, 6, tuberculosis, 9.

The Laboratory of Hygiene made 2551 examinations, the details of which are

Examinations for diphtheria bacilli	112
“ “ typhoid fever (Widal reaction)	50
“ “ undulant fever	117
“ “ gonococci in pus	121
“ “ tubercle bacilli	231
“ “ syphilis	1257
“ of water, bacteriological	227
“ “ water, chemical and bacteriological	156
“ “ milk, market	133
“ “ milk, submitted for microscopic only	2
“ “ foods	27
“ for courts, autopsies	3
“ “ courts, miscellaneous	34
Autopsies to complete death returns	3
Miscellaneous examinations	78

The director of the Division of Venereal Diseases reports 20 cases of gonorrhea and 59 cases of syphilis. Eleven speaking trips were made, chiefly to parent-teacher groups and to high schools.

The director of the Crippled Children's Division reports a total of 158 visits made by nurses and the social worker. At the beginning of the month, 6 patients were in hospitals, 9 were admitted and 12 discharged. Nine patients were in convalescent homes at the beginning of the month, and 1 patient was discharged from Warm Springs, Georgia. Fifty-six pieces of apparatus were fitted, 24 orthopedic corrections were made to shoes, and 2 pieces of apparatus were repaired. The occupational therapy director reports sales for the month of \$78.50.

The Public Health Nursing Division reports the opening of a new unit for Morristown and Stowe on October 15, with headquarters in Morrisville. Conferences and committee meetings took up the greater part of the month and the director spoke before ten of the county home demonstration finish up meetings.

The director of the Maternal and Child Health Division attended the meeting of the American Dental Association in St. Louis, also the meetings of the American Public Health Association and the American Pediatric Society. Six hundred and forty-seven baby booklets, 300 diphtheria consent cards and 451 notifications of birth registration were sent out during the month.

## MISCELLANY

### COMMUNITY FUND CAMPAIGN

During hard times—whether of depression or recession—and their years of aftermath there has been a greater call for free and partially free medical and hospital services.

Statistics are not dry when they reveal that in the past three years the number of patients given free or low price hospital and clinical care in those Metropolitan-district health services that receive aid from Greater Boston's Community Fund has almost doubled.

That the burden on the hospitals is excessive may be gleaned from the fact that last year member hospitals of the Greater Boston Community Federation used nearly \$100,000 from their endowment funds to meet current expenses of care for destitute and low income persons. The 114 agencies and federations participating in Greater Boston's 1939 Community Fund Campaign give not only hospital, dispensary and clinical services, but convalescent, maternity and home nursing care. There are social services for old and young, the deaf and the blind, services to give the underprivileged a fair chance in life, services designed to turn delinquency into constructive citizenship, services to train the handicapped to compete on an even basis with normal persons. Every phase of human well-being is within the Federation's scope, with much of it devoted to preventive medicine. Yet the health needs of the destitute and low income groups are not adequately met—a serious fact, not only for them but for the general health and economic strength of the whole community. In fact, if only to promote the general safety, wholesomeness and stability of community life, the valuable constructive work of all the agencies should be strengthened.

The three year-old Federation has been going steadily forward in its efforts to bring the agencies up to adequate support, after their years of reduced income due to depression. Because of this, and because more organizations are in the campaign this year, more givers and larger subscriptions are needed for Greater Boston's Community Fund Campaign, which, starting January 23, extends through February 7. Looking forward to a generous over subscription of the minimum goal of \$4,645,000, Stuart C. Rand, general chairman, and every member of his able

corps of assistants are asking all citizens to give till it feels good'

Each year the medical profession has been asked to pledge of its means, despite the fact that every day of the year the doctor gives freely of his services to many from whom he can never hope to obtain a cent. The doctors have responded, perhaps because they are so accustomed to answer the call of human need that the Community-Fund appeal finds their hands automatically reaching for a pen to sign a subscription

Few, if any, physicians feel that their free work entitles them to exemption from the Community Fund call, no more than it exempts thousands of other volunteers who give generously of their time and energy throughout the year to the work of social service agencies. Physicians and surgeons know, too, that hospitals, clinics and convalescent institutions give young members of the profession experience and training they could get nowhere else, and that they may bring their private patients to these institutions for the benefit of the judgment and skill of the older men who are the attending physicians and surgeons and for the use of the highly specialized and expensive equipment that would not otherwise be available were it not for the whole-hearted support of such institutions by the community

This year's group of one hundred and seven doctors lending their efforts to make the 1939 Community Fund Campaign a success is headed by Dr William B Breed. The ten subcommittees are as follows

Vice-chairman, Dr Herrman L. Blumgart. Committeemen Drs. Charles H. Bradford, Newton C. Browder, John G. Downing, Henry E. Groden, Abraham Myerson, Max Rutvo, Virgil G. Casten, Hugh C. Donahue, Edward Harding, Francis Rouillard.

Vice-chairman, Dr Earle M. Chapman. Committeemen Drs. Hollis L. Albright, Frank E. Barton, G. Marshall Crawford, Allen P. Joslin, John V. Leech, Alexander Marble, Thomas H. Peterson, Samuel N. Vose, James K. Wardwell, Richard G. Whiting

Vice-chairman, Dr R. Cannon Eley. Committeemen Drs. Geoffrey Edsall, Louis K. Diamond, William T. Green, Randolph K. Byers, Henry E. Gallup, F. William Marlow, Jr., Robert Sanderson.

Vice-chairman, Dr Marshall N. Fulton. Committeemen Drs. James M. Baty, Edward M. Cole, Lowrey F. Davenport, Eugene C. Eppinger, John P. Hubbard, T. Duckett Jones, Robert T. Monroe, William T. Salter, Reuben Z. Schulz, Harry A. Warren

Vice-chairman, Dr Robert J. Joplin. Committeemen Drs. Perry C. Baird, Jr., Richard Chute, Walter E. Garey, Jeremiah E. Greene, Sylvester B. Kelley, G. Douglas Krumbhaar, Lendon Snedeker, J. Sydney Stillman, Thomas V. Urmy, Charles B. Kimmel

Vice-chairman, Dr Alfred O. Ludwig. Committeemen Drs. Donald V. Baker, John W. Cass, Jr., Howard C. Coggeshall, John R. Frazoo, Ward I. Gregg, Alfred Krane, James H. Means, Michael E. Murray, Paul Norton, John W. Zeller

Vice-chairman, Dr William B. Stevens. Committeemen Drs. John A. Abbot, Louis Arkin, William Dameshek, Julian C. Gant, Joseph Lentine, Jacob Lorman, Walter S. Levenson, Jacob H. Swartz, George S. Speare, Abraham Rudy

Vice-chairman, Dr Charles L. Swan, Jr. Committeemen Drs. Arthur Berk, Benedict F. Boland, James E. Fish, Ashton Graybiel, Reed Harwood, Eugene E. O'Neil, Clifford C. Franseen, Weston T. Buddington.

Vice-chairman, Dr Soma Weiss. Committeemen Drs. Leo Alexander, Seth F. Arnold, Austin M. Brues,

John T. Edsall, Maxwell Finland, George E. Heels, Franc D. Ingraham, Paul Kunkel, G. Kenneth Mallory, Merrill C. Sosman

Vice-chairman, Dr Greene Fitzhugh. Committeemen Drs. Henry Clifford, Benjamin Cornwall, Moses Lurie, Bretney Miller, John P. Monks, John L. Newell, Langdon Parsons, Somers Sturges, Milton Thompson, Claude E. Welch

## TRICHLORETHYLENE DEGREASERS

A common method of cleaning metal objects coated with oil, grease or similar substances is by means of an organic solvent applied in a degreaser. The usual degreaser is a tank suitable in size to the work, in which the solvent is heated to boiling at the bottom and the vapor subsequently condensed by water cooling at a higher level. Trichlorethylene is the solvent almost universally used. Questions as to the effect of such a machine on the health of workers employed in its vicinity are frequently raised

When idle, even though the tank be open, the escape of vapor from a properly adjusted degreaser is not great unless there is a strong current of air over the top of the tank. The introduction and removal of objects into and from the machine greatly increase the escape of solvent vapor. It has been found, however, that small and medium-sized degreasers, properly operated and not overloaded, do not constitute an important health hazard, even when used continually, provided that they are placed in a reasonably well-ventilated room. Larger machines—those of over 12 square feet cross-sectional area—may on the other hand subject the operator to high concentrations of solvent vapor, especially if used continually. The cleaning out of degreasers, particularly those in which the worker must enter the tank in the process, may involve exposures to very high concentrations of trichlorethylene vapor for limited periods of time.

Trichlorethylene vapor in high concentrations will cause unconsciousness and even death, but the ill effects of repeated exposure to small concentrations are apparently less severe than those of most other chlorinated hydrocarbons. Much of the trouble caused by trichlorethylene in the past has been attributed to impurities not present in the product now commercially available. Continuous exposure to concentrations too low to cause immediate effects, such as headaches and dizziness, may nonetheless eventually injure the worker. Addiction to trichlorethylene not infrequently follows continued exposure to high concentrations of vapor.

The following rules for the safe operation of degreasers are advised

- 1 Place the degreaser in a high posted, good-sized room, if possible. If only a small room is available, install one or more window fans to improve the general ventilation
- 2 Be sure that there is an adequate supply of cooling water for the condenser of the degreaser
- 3 Never allow the machine to be so overloaded that the vapor line rises above the condenser tubes
- 4 Make sure that the process of cleaning out the tank does not involve an excessive exposure to solvent vapor. This can usually be accomplished by airing out the machine after withdrawal of the liquid, but additional precautions may sometimes be necessary. Cartridge respirators do not give adequate protection if the exposure is heavy. Hose masks or air line respirators may be used if they do not impede the worker too greatly

- 5 Local exhaust ventilation, through slots along the edges of the tank, should be necessary only in extreme cases. Such ventilation will reduce the concentration of solvent vapor in the air but is likely to increase the loss of solvent.
- 6 If the odor of the solvent persists in the vicinity of the machine, or if workers complain of ill effects, notify this office and ask for an air analysis. The atmospheric concentration of trichlorethylene vapor should not exceed 200 parts per million parts of air.

*Division of Occupational Hygiene,  
Massachusetts Department of Labor and Industries*

## NOTES

Dr. Riley H. Guthrie, chief executive officer of the Boston Psychopathic Hospital, has been appointed first assistant physician at Saint Elizabeths Hospital, Washington, District of Columbia; it has been announced by Dr. Winfred Overholser, superintendent of the hospital. Dr. Guthrie received the degree of Doctor of Medicine from the University of Tennessee School of Medicine in June, 1921. He served on the staff of the State Hospital at Little Rock, Arkansas, for three years, spent two years in private practice, and then resumed institutional work as assistant physician at the State Hospital at Massillon, Ohio. Following this he was appointed medical officer at the Boston Psychopathic Hospital, serving for one year, and for six years thereafter was assistant superintendent of the Monson State Hospital at Palmer, Massachusetts. In June, 1935, he was appointed assistant to the Commissioner of Mental Diseases of Massachusetts, and in November of the same year chief executive officer of the Boston Psychopathic Hospital. He is a diplomate of the American Board of Psychiatry and Neurology, and has contributed extensively to the literature of psychiatry. In a recent countrywide competitive examination held by the United States Civil Service Commission he received the highest rating given.

Middlesex University announces the appointment of Dr. Louis Bergmann, of Vienna, to a full time teaching position in the School of Medicine, as associate professor of anatomy. Dr. Bergmann received his M.D. degree from the University of Vienna, where he served as assistant to Prof. Julius Tandler in the anatomical department. He accompanied Prof. Tandler in 1934 to China, where he was associated with the National Medical College of Shanghai and taught anatomy at the Hunan Yale Medical College in Changsha and at the Army Medical College in Nanking.

## CORRESPONDENCE

### TRANSFUSION OF INCOMPATIBLE BLOOD

*To the Editor*—Your editorial and the letter from Dr. Dameshek, printed in a recent issue of the *Journal*, calling attention to the dangers of incorrect blood grouping, surely come at an opportune time. I should like to express my agreement with your opinions, and also call attention to other dangers of a slightly different sort which may result from incompetent blood group determinations.

It seems to me that part of the trouble is traceable to the lack of properly qualified experts in this field. This in turn is perhaps due to the fact that blood grouping,

though recognized as important, is scientifically treated as a sort of stepchild, often being taught as a part of some subject not closely related. There are no chairs of blood grouping in our schools, and it is difficult for a person whose research has been chiefly concerned with blood grouping to get an academic position, unless he has a second string to his bow. Consequently there is little financial stimulus for promising young men to devote themselves to the study of this important, and fascinating, subject. This is in unfortunate contrast to the situation which prevails in some foreign countries, for example, the U. S. S. R., where the chief cities have institutes specifically devoted to the study of blood groups and blood transfusion.

It is perhaps not necessary that all routine blood group determinations be carried out by experts who have spent years in a study of the subject, though it would certainly be desirable that the work be done by persons with better training than that now routinely available. But it would seem highly important that such experts be available, at least one in every city, so that their advice could be sought, as in the preparation of serum and in the not too infrequent cases of peculiar reactions encountered in blood grouping.

In one such case, a young man who claimed that his blood group had changed from Group O to Group A was retested in my laboratory, with the result that he was found to belong to the weakly reacting type of Group A, designated A<sub>2</sub>. It is well known that some Group B serums may lack (or lose after brief storage) the agglutinin for this type of blood, so it is likely that the technician in the first hospital (one of the large hospitals in this city) used such a serum and wrongly classified the young man as belonging to Group O. The startling thing about this story is that, according to his own account, the young man had been used twice as a donor, under the impression he belonged to Group O!

It is probably no exaggeration to say that not one in fifty of those who routinely attempt to determine blood groups could give an intelligible account of the sub-groups A<sub>1</sub> and A<sub>2</sub>, of the independent blood types M, MN and N, or of the possible kinds of irregular reactions. In 99 cases out of 100, this knowledge is not needed, but in the hundredth case it may mean the difference between life and death for the patient.

A further danger to the public lies in the fact that many grossly unqualified persons are willing to constitute themselves experts in this important field, when as a matter of fact they are almost entirely without training in it. It should be emphasized that the possession of a medical or Ph.D. degree, or even a lifetime of experience in some other branch of medical science, does not constitute a person an expert in blood grouping, which is itself a special and intricate subject, with its own discipline and large body of literature.

It is to be hoped that something can be done to remedy this situation, perhaps departments or even whole institutions devoted to the study of this important subject will ultimately be established. In the meantime it would seem that the least that can be done is to come to some sort of agreement as to the qualifications which a person must possess before being permitted to carry out clinical blood group determinations and what qualifications constitute an expert in the subject.

WILLIAM C. BOYD, Ph.D.

Boston University School of Medicine,  
Boston

NOTICES

ANNOUNCEMENT

EDWARD S. STONE, M.D., announces the opening of an office at 416 Marlborough Street, Boston

MEDICAL CLINIC AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 p m on Thursday, January 26, in the amphitheater of the Peter Bent Brigham Hospital, Dr Samuel A Levine, assistant professor of medicine, Harvard Medical School and senior associate in medicine, Peter Bent Brigham Hospital, will give a medical clinic. Practitioners and medical students are cordially invited to attend

WINTHROP COMMUNITY HOSPITAL

The next meeting of the staff of the Winthrop Community Hospital will be held at the hospital on Thursday evening, January 26, at 8 30

Dr Joseph H. Burnett will speak on "Fractures and Sprains of the Ankle Joint: Their diagnosis and treatment." The talk will be illustrated by practical demonstrations

Nurses and medical students are cordially invited to attend.

J J ABRAMS M.D., *Secretary*

SYMPOSIUM ON THE PUBLIC-HEALTH SIGNIFICANCE OF THE VIRUS AND RICKETTSIAL DISEASES

The faculty of the Harvard School of Public Health is offering a short course of lectures, clinics and demonstrations on the virus and rickettsial diseases, with special emphasis on their public-health significance, to be held at the school during the week of June 12 17, 1939. Lectures on the etiology, epidemiology and methods of control of these diseases, given by members of the faculties and by former students of the Harvard School of Public Health and of the Harvard Medical School, will occupy five mornings. Special clinics and demonstrations will be given each afternoon. In some instances these demonstrations will be continued through the week, so that all the members of the symposium can attend. On the last morning, a panel discussion will be held on the three main topics presented in the symposium.

The fee for the course will be \$25 00, payable at any time up to June 12. Enrollment, however, should be arranged before June 1, as facilities for many of the clinics and demonstrations are limited. The lectures will be published later in a single volume, which will be sent to each person who has registered for the course.

Further information may be had by writing to the Secretary of the School of Public Health, 55 Shattuck Street, Boston

ROBERT B BRIGHAM HOSPITAL

There will be an open meeting at the Robert B Brigham Hospital, 125 Parker Hill Avenue, Roxbury, Tuesday evening, February 7, at 8 00

Dr Loring T Swann will give an illustrated talk on "Prevention and Correction of Deformities in Chronic Arthritis"

All doctors and medical students are cordially invited to attend.

EDITH I COV, *Superintendent*

SUFFOLK DISTRICT MEDICAL SOCIETY

There will be a meeting of the Suffolk District Medical Society at the Boston Medical Library, 8 Fenway, on Wednesday evening, January 25, at 8 15

PROGRAM

A DISCUSSION OF RECENT PROGRESS IN DIABETES  
(arranged by Dr E. P Joslin)

Resume of the Diabetic Situation Here and Elsewhere.  
Dr E. P Joslin.

Treatment with Diet and Protamine Zinc Insulin in Hospital and Home. Dr A. P Joslin.

Crystalline Insulin. Dr Alexander Marble.

Diabetic Coma. Dr Howard F Root.

Peculiarities in Therapy of Diabetic Children on Two Continents. Dr Richard Wagner.

Hypoglycemia. Dr Henry Baker and Dr Alexander Marble.

A Resume of Dr Harvey Cushing's Patients with Acromegaly and Young's Experimental Pituitary Diabetes. Dr Howard F Root.

Thirty Nine Pregnancies in Diabetics in 1938 and Studies Thereon. Dr Priscilla White.

The Emphasis Shifts from Treatment to Prevention and Early Detection of Diabetes. Dr E. P Joslin.

The Future. Dr E. P Joslin.

JOHN P MONKS, M.D., *Secretary*

BOSTON GASTROENTEROLOGICAL SOCIETY

The next meeting of the Boston Gastroenterological Society will be held in the auditorium of the Joseph H. Pratt Diagnostic Hospital, Bennet Street, at 12 o'clock noon, Wednesday, January 25, Dr Hilbert F Day will preside. Dr Samuel Proger will direct inspection of the new hospital either before or after the program. Miss Frances Stern will present a dietetic exhibition

PROGRAM

Pancreatic Enzymes. Dr Joseph H. Pratt.

Lesions About the Pylorus. Dr Jacob J Schloss.

Hemorrhage Due to Peptic Ulcer. Dr Henry H. Lerner.

Chronic Duodenal Ileus. Dr Katherine S Andrews.

C W MCCLURE, M.D., *Secretary*

MASSACHUSETTS PSYCHIATRIC SOCIETY

There will be a meeting of the Massachusetts Psychiatric Society at the Boston Psychopathic Hospital, Friday evening, January 27, at 8 00

Judge John F Perkins of the Boston Juvenile Court will speak, and Drs Abraham Myerson and Kenneth J Tillotson will present a paper "Theory and Practice of the Total-Push Method in Schizophrenia."

W FRANKLIN WOOD, M.D., *Secretary*

BOSTON MEDICAL LIBRARY

The annual meeting of the Boston Medical Library will be held in Sprague Hall at 8 Fenway, Tuesday afternoon, January 24, at 4 30 o'clock. Reports will be received from the Board of Trustees, the Treasurer, the Librarian and from the various committees. Two vacancies on the Board of Trustees are to be filled.

All fellows of the Library are urged to attend

JAMES M FAULKNER, M.D., *Secretary*

## NORFOLK DISTRICT MEDICAL SOCIETY

A regular meeting of the Norfolk District Medical Society will be held in the Evans Auditorium of the Massachusetts Memorial Hospitals, 78 East Concord Street, Boston, on Tuesday evening, January 31, at 8 30

## PROGRAM

Erythroblastosis Foetalis Dr H. C. Petterson  
Presentation of a Case of Osteomyelitis of the Frontal Bone. Dr L. F. Johnson.  
Demonstration of Technic Employed in the Placental Block Bank. Dr F. E. Barton  
Cardio-omentopexy for Revascularization of the Ischemic Heart. Medical—Dr Ashton Graybiel  
Surgical—Dr J. W. Strieder  
Hyperthyroidism and Heart Disease Dr H. M. Clute  
FRANK S. CRUICKSHANK, M.D., Secretary

## ARLINGTON AND BELMONT MEDICAL CLUBS

A combined meeting of the Arlington and Belmont medical clubs will be held at Hambury Hall, Ring Sanatorium and Hospital, on Tuesday evening, January 24, at 8 00

The report of a study on "The Use of Insulin in Toxic Hallucinations" will be presented by Drs Hosea W. McAadoo and Curtus T. Prout of the Ring Sanatorium staff

Following the program a buffet supper will be served.

MICHAEL F. NIGRO, M.D., Secretary  
Arlington Doctors Club  
LEO A. BLACKLOW, M.D., Secretary  
Belmont Medical Club

## SALEM HOSPITAL PUBLIC-HEALTH LECTURES

The Salem Hospital will conduct a series of Sunday afternoon lectures this winter on medical subjects of general public interest. The purpose of these lectures is to afford the layman an opportunity to gain an accurate knowledge of methods for the protection of his health and the prevention of illness

The lectures will be free to the public and will be held in the auditorium of the Nurses Home during January, February and March, at 4 00 p. m. The first lecture was given January 15 by Dr. Walter G. Phippen, who spoke on 'Liver Complaint and Gall Bladder Disease'

The remainder of the program is as follows

January 22 Skin Evidences of General Ill Health. Dr E. Lawrence Oliver  
January 29 How Are Your Kidneys? Dr Henry D. Stebbins  
February 5 Your Teeth Dr Edgar A. Wright.  
February 12 The Position of X Ray in Present Day Medicine. Dr Stanley A. Wilson.  
February 19 Watch Your Diet. Miss Edith L. Hoadley  
February 26 The Health of the Preschool Child. Dr Robert T. Moulton.  
March 5 Why Nerves? Dr William V. McDermott.

## AMERICAN BOARD OF OPHTHALMOLOGY

The American Board of Ophthalmology announces an important change in its methods of examination of candidates for the board's certificate.

Examinations will be divided into two parts. Candidates whose applications are accepted will be required to pass a *written* examination which will be held simultaneously in various cities throughout the country approximately sixty days prior to the date of the *oral* examination.

The *written* examination will include all the subjects previously covered by the practical and oral examinations.

*Oral* examinations will be held at the time and place of the meeting of the American Medical Association and of the American Academy of Ophthalmology and Otolaryngology, and occasionally in connection with other important medical meetings. The *oral* examination will be on the following subjects: external diseases, ophthalmoscopy, pathology, refraction, ocular motility, and practical surgery.

Only those candidates who pass the *written* examination and who have presented satisfactory case reports will be permitted to appear for the *oral* examination.

Examinations scheduled for 1939: *written* March 15 and August 5, *oral*, St. Louis, May 15, and Chicago, October 6

Applications for permission to take the *written* examination March 15 must be filed with the secretary not later than February 15

Application forms and detailed information should be secured at once from Dr. John Green, secretary, 6330 Waterman Avenue, St. Louis, Missouri

## HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Tuesday, January 24, in the Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance), at 8 15 p. m.

## PROGRAM

Presentation of cases

Some Clinicoroentgenological Correlations Dr Merrill C. Sosman and Dr Samuel A. Levine.

Medical students and physicians are cordially invited to attend.

## SOCIETY MEETINGS AND CONFERENCES

## CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, JANUARY 23

## MONDAY, JANUARY 23

8 15 p. m. New England Heart Association Boston City Hospital Mallory amphitheater

## TUESDAY, JANUARY 24

9 10 a. m. Joseph H. Pratt Diagnostic Hospital X-ray demonstration Dr Alice Ettinger

\* 10 a. m. 12 30 p. m. Tumor Clinic Boston Dispensary

4 30 p. m. Boston Medical Library annual meeting Sprague Hall

8 15 p. m. Harvard Medical Society Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance)

## WEDNESDAY, JANUARY 25

9 10 a. m. Joseph H. Pratt Diagnostic Hospital Hospital case presentation Dr S. J. Thannhauser

12 m. Clinicopathological conference Children's Hospital amphitheater

12 m. Boston Gastroenterological Society Auditorium of the Joseph H. Pratt Diagnostic Hospital Bennet Street Boston

8 15 p. m. Suffolk District Medical Society Boston Medical Library

## THURSDAY, JANUARY 26

8 30-9 30 a. m. Exchange visit, Surgical and Orthopedic Staffs of the Peter Bent Brigham and Children's hospitals held this week at the Children's Hospital Orthopedic

9 10 a. m. Joseph H. Pratt Diagnostic Hospital Medical social service case presentation District Service and Social Service Staff

3 30 p. m. Medical clinic at the Peter Bent Brigham Hospital

## FRIDAY JANUARY 27

9 10 a m. Joseph H Pratt Diagnostic Hospital Examination of Coronary Circulation by the Injection of a Radio-Opaque Substance. Dr F T Fulton.

\*10 a m. 12.30 p m. Tumor clinic. Boston Dispensary

8 p m Massachusetts Psychiatric Society Boston Psychopathic Hospital.

## SATURDAY JANUARY 28

\*9 10 a m. Joseph H Pratt Diagnostic Hospital Hospital case presentation. Dr S J Thannhauser

\*10 a m 12 m Staff rounds of the Peter Bent Brigham Hospital Conducted by Dr Henry A. Christian.

## SUNDAY JANUARY 29

4 p m. Illustrated public health lecture, Faulkner Hospital auditorium Recent Advances in the Treatment of Boce Injuries Dr Gordon M Morrison.

4 p m. Free public lecture, Harvard Medical School amphitheater of Building D Food and Drugs. Safe and unsafe. Dr J J Durrett. U S Food and Drug Administration

\*Open to the medical profession

## BOOK REVIEWS

*Interns Handbook A guide especially in emergencies for the intern and the physician in general practice* M. S. Dooley. Second edition, revised and reset. 523 pp Philadelphia, London, Montreal J B Lippincott Co, 1938 \$3.00

The first edition of this handbook was published in 1929. The *Journal* (202-97, 1930) reviewed it favorably, saying that the book contained a great deal of valuable information presented clearly in concentrated form.

The first part included a physician's drug list and an outline of the emergency treatment of drug poisoning. The second part outlined standard clinical procedures for

history taking, dietary, routine laboratory tests and techniques for safeguarding laboratory specimens. The *Journal of the American Medical Association* (93 1173, 1929) termed it a guidebook which would enable interns and clinical clerks to adapt themselves easily to hospital routine and to acquire ability to render effective service. This seemed a fair characterization.

The second edition is a new model. It is larger than the first—523 pages against 235, its contents have been rearranged. Now it begins with a description of the intern's relation to the hospital, tells him how to become housebroken, how to procure necropsies, what to read. The second part deals with the laboratory and is a handy compendium of clinical pathology. The third section concerns medicine, the fourth, surgery, and the fifth, therapy, where once more the emergency treatment of drug poisoning is included. The sixth section deals with nursing, wherein are described simple methods for improvising backrests or cradles, for turning a helpless patient and for bedmaking, all taken as a matter of course in hospital life but which are not so simple when young Lydgate goes alone to his first sick patient's home with no equipment but his own common sense and the recollection of how things were done when he was an intern.

All this information once again is well printed in legible type, is presented in clear, concentrated form, so arranged that quick reference is possible, and is compressed into a small-sized volume which easily fits into one's bag or pocket. The *Journal* is glad to repeat the book is one of the best of its kind and should be useful to practitioners as well as to interns.

*Meningiomas. Their classification, regional behaviour, life history and surgical end results.* Harvey Cushing. 785 pp. Springfield, Illinois: Charles C Thomas, 1938. \$15.00.

It has long been hoped that Dr. Cushing would, now that he has retired from the active practice of surgery, review his experiences with various types of brain tumors and record not only the results but his methods of handling these dangerous and destructive lesions. Away from the two hospitals where his work was done and giving much of his time to literary work and the cataloguing of his large library of historical works, many must have thought that no effort on his part would result in a book such as he has produced on meningiomas. He not only brought to his desk in New Haven the records by photostat of all his patients, but he also followed them as carefully as if each were still calling at his office. A total of 313 cases, each followed to death or, if living, to the present time, with accurate notes of the conditions at postmortem or reports on the clinical conditions of all living patients, is presented in this monograph. At once it may be said that no surgeon has ever had such a complete series of case histories to deal with, for no surgeon up to Dr. Cushing's time ever followed all his cases so persistently. Great credit for this should go also to the junior author, Dr. Eisenhardt, who has shown as much zeal in following patients as in working out the details of the pathology of meningiomas.

The series of cases, operated on from October, 1903, to October, 1932, constitutes the bulk of the volume. Each case history is given in detail with a wealth of illustrations—roentgenograms, operative sketches, photographs of tumors, photographs of patients and pictures showing the microscopic appearance of the lesions. In addition, there are chapters on pathology, tumor incidence, the types of tumors according to their location, diagnosis and operative technic and a complete bibliography and index.

The introductions to many chapters contain historical material, often illustrated. An unusual feature is the recording of the actual name of each patient and the giving over of separate chapters to the 'Case of Timothy Donovan' and the 'Case of Dorothy Russell', two brave patients, each with recurrent meningiomas requiring repeated operations. With humanity seldom found in text books and with true literary skill, Dr. Cushing has depicted the medical lives of two heroes, both sure to have a permanent place in the annals of medical history.

In regard to meningiomas in general the following points are brought out: solitary tumors have favorite loci of origin, tumors of each locus behave in much the same way, certain meningiomas tend to recur, 172 of the 313 patients were alive in 1937—132 with a period of five years or more after operation, the survival period may be twenty or more years, case mortality was greatly reduced as the result of electrosurgical methods introduced in 1927, meningiomas may be classified according to nine pathological types, with variants, the types often described as epitheliomatous or sarcomatous have as favorable a prognosis as the 'dural endotheliomas' or the fibroblastic tumors. These and many other points are clearly brought out.

A word should be said in regard to the publisher and printer. The illustrations, skillfully placed on each page, are remarkably clear, the tables finely arranged and the spacing about the figures carefully placed. Each page has a pleasing appearance as well as boldly bringing out the illustrative points by both pictures and variations in type. In a 785 page book with 685 illustrations and numerous charts, only one unimportant error was found in a fairly complete reading of the text.

The reviewer is left with the impression that a book of more than ordinary value has come to his hand. Every page shows the master surgeon and the literary ability of the author. To be sure, no one else had so much knowledge of this type of tumor as did the author, but, on the other hand, who but Dr. Cushing could write so clearly so frankly of his mistakes and so charmingly about his patients? Surgically, this is a book of the first importance, historically, it is a classic.

*The Home Book of Medicine.* David Polowe. 581 pp. New York: Greenberg, 1938. \$2.75.

The purpose of the author of this book is to have it included in the family library for the instruction of those who may be responsible for the health of the household.

With this in view a brief description of the construction of the human body is presented, together with the essential facts concerning the functions of the important organs and systems. After a discussion of the etiology and prevention of disease advice is given about the selection of a doctor and what should be done under certain circumstances before the patient is under professional supervision.

The chapters next in order are devoted to nursing and the care of convalescent patients and to a consideration of chronic diseases. The remaining pages—over half the book—deal with the symptomatology, diagnosis and treatment of diseases, accidents and other emergencies, approved diet lists and co-ordinate subjects.

The book is well written and in a concise fashion covers most of the common phases of illness, but the question as to the wisdom of trying to teach non-medical persons so much of medicine seems pertinent because some people may be led to feel that the employment of a doctor in a given case is not required, with disastrous results.

NUMBER 4

## TREATMENT OF CHRONIC ALCOHOLISM WITH AMPHETAMINE (BENZEDRINE) SULFATE\*

WILFRED BLOOMBERG, M.D.†

BOSTON

AMPHETAMINE (Benzedrine) sulfate was introduced into therapeutics in 1935 by Prinzmetal and the author<sup>1</sup> as an effective agent in the prevention of symptoms in narcolepsy. Since that time it has been used for a great variety of conditions, and has been found to be of value in relaxation of the gastrointestinal tract<sup>2</sup> and in the treatment of postencephalitic Parkinsonism<sup>3</sup> and obesity of neurotic origin.<sup>4</sup> Its efficacy in narcolepsy has been confirmed.<sup>5</sup> In addition, numerous reports have established the fact that amphetamine sulfate has a striking effect on the mood in psychotic and psychoneurotic patients and in normal individuals,<sup>6</sup> and on the intelligence, or rather perhaps on mental alertness, as demonstrated by its influence on psychometric scores.<sup>7</sup>

Because of the "lift" given by amphetamine sulfate, because it was found to be extremely effective in relieving "hangover" on the morning following excessive indulgence in alcohol, and because taken beforehand the drug appeared to increase the ability to consume alcohol without intoxication, it seemed reasonable to try its effect as a replacement for alcohol in the chronic alcoholic. It seems probable that at least some alcoholics drink in order to make themselves feel more adequate to their situations. A mild alcoholic "glow" overcomes their feelings of inferiority, it loosens their tongues and their wit, and permits them to vanquish shyness and embarrassment. The fact that this is only a transient state in the excessive consumption of alcohol and is followed by an exaggeration of all the unpleasant feelings, plus indeed depression and certain physical symptoms, such as headache, nausea, dizziness and gastrointestinal disturbance, has notoriously never been a sufficient reason to hinder the chronic alcoholic from

overindulgence. Nor does the fact that the secondary depression is severe prevent him from attempting to drown his primary depression in liquor. Because amphetamine sulfate modified the mood it was hoped that it would affect the situation of the chronic alcoholic.

In addition to these general considerations, there is the fact that the central stimulating effect of amphetamine sulfate was first noted by Alles and Prinzmetal<sup>8</sup> when it awakened barbitalized dogs. In patients suffering from drug comas due to the barbiturates, the opiates or even paraldehyde, amphetamine sulfate has proved useful. Since the action of alcohol is at least akin to that of these sedative and narcotic drugs, such facts gave additional basis for an attempt to elicit an antagonism between alcohol and amphetamine.<sup>9</sup>

### METHOD

Patients were seen partly in office practice, referred by other physicians or by other patients, and partly at a clinic at the Boston City Hospital, referred by other outpatient and house services. All chronic alcoholics who could be persuaded to try the treatment received it. Only 1 refused treatment, and his case is not included in the following reports. The only selection practiced was refusal to treat 2 patients, 1 a private and 1 a clinic case, both of whom had already stopped drinking. They had done this so long before we saw them that any results obtained would have no significant value in this experiment, since it would be impossible to attribute the cessation of drinking to treatment. Other than these 2, the cases were entirely unselected, except in so far as selection took place when patients were referred, because other methods had so far failed.

An attempt was made to avoid all formal psy-

From the Neurological Unit, Boston City Hospital, and the Department of Neurology, Harvard Medical School.

This study was aided by a grant from the Smith Kline and French Laboratories, Philadelphia.

†Instructor in neurology, Harvard Medical School; junior visiting neurologist, Boston City Hospital.

\*After this study was begun, reports by Reifstein and Davidson<sup>10</sup> and by Wilbur, MacLean and Allen<sup>11</sup> on the use of amphetamine sulfate in acute alcoholism have given further confirmation to the above theoretical considerations.

history taking, dietary, routine laboratory tests and techniques for safeguarding laboratory specimens. The *Journal of the American Medical Association* (93 1173, 1929) termed it a guidebook which would enable interns and clinical clerks to adapt themselves easily to hospital routine and to acquire ability to render effective service. This seemed a fair characterization.

The second edition is a new model. It is larger than the first—523 pages against 235, its contents have been rearranged. In regard to meningiomas in general the following points are brought out: solitary tumors have favorite loci of origin, tumors of each locus behave in much the same way, certain meningiomas tend to recur, 172 of the 313 patients were alive in 1937—132 with a period of five years or more after operation, the survival period may be twenty or more years, case mortality was greatly reduced as the result of electrosurgical methods introduced in 1927, meningiomas may be classified according to nine pathological types, with variants, the types often described as epitheliomatous or sarcomatous have as favorable a prognosis as the 'dural endotheliomas' or the fibroblastic tumors. These and many other points are clearly brought out.

A word should be said in regard to the publisher and printer. The illustrations, skillfully placed on each page, are remarkably clear, the tables finely arranged and the spacing about the figures carefully placed. Each page has a pleasing appearance as well as boldly bringing out the illustrative points by both pictures and variations in type. In a 785 page book with 685 illustrations and numerous charts, only one unimportant error was found in a fairly complete reading of the text.

The reviewer is left with the impression that a book of more than ordinary value has come to his hand. Every page shows the master surgeon and the literary ability of the author. To be sure, no one else had so much knowledge of this type of tumor as did the author, but, on the other hand, who but Dr. Cushing could write so clearly, so frankly of his mistakes and so charmingly about his patients? Surgically, this is a book of the first importance, historically, it is a classic.

*The Home Book of Medicine.* David Polowe. 581 pp. New York: Greenberg, 1938. \$2.75.

The purpose of the author of this book is to have it included in the family library for the instruction of those who may be responsible for the health of the household.

With this in view a brief description of the construction of the human body is presented, together with the essential facts concerning the functions of the important organs and systems. After a discussion of the etiology and prevention of disease, advice is given about the selection of a doctor and what should be done under certain circumstances before the patient is under professional supervision.

The chapters next in order are devoted to nursing and the care of convalescent patients and to a consideration of chronic diseases. The remaining pages—over half the book—deal with the symptomatology, diagnosis and treatment of diseases, accidents and other emergencies, approved diet lists and co-ordinate subjects.

The book is well written and in a concise fashion covers most of the common phases of illness, but the question as to the wisdom of trying to teach non-medical persons so much of medicine seems pertinent because some people may be led to feel that the employment of a doctor in a given case is not required, with disastrous results.

drink—had been 6 days. In the previous 2 or 3 years he had averaged sixteen drinks of gin daily. He was obviously under the influence of alcohol at the time of the first interview.

He was started on amphetamine sulfate, 10 mg twice daily. On the day after his first visit he stopped drinking. During the next few months he was seen often, and constantly reiterated that he had no desire for alcohol, felt well and had no untoward symptoms. In November, 1937, he went on a 3-month cruise to the tropics as a passenger on a freighter. On his return in March, 1938, he reported that he was still under no temptation to drink. He had had an occasional glass or two of beer and one or two highballs during the voyage, but always in company and because the water was thought to be bad, he had not been drunk nor had any craving for alcohol, his small amount of drinking he characterized as 'social drinking'. He had continued to take amphetamine sulfate daily throughout the trip.

On March 31 he again reported that he was not drinking and declared that the present treatment was the most effective he had ever had. However, on April 6 the patient reported that he had been drinking fairly heavily for 3 or 4 days. At the beginning of this period the culminations of a financial tangle and a difficult domestic situation had occurred coincidentally. He had stopped taking amphetamine sulfate and started drinking—he could not say exactly why. He insisted that his daily consumption during this period was far less than his average before treatment. He thought that the episode was over. He was started again on amphetamine sulfate, 40 mg daily, and the drinking stopped. He was seen again on September 29 when he said he had not been drinking since the last visit, except for a few glasses of beer during July, which he considered as 'social drinking'.

On October 26 the patient's wife reported that he had been drinking heavily for several days. On November 3 he himself came in and stated that he had drunk nothing for about 7 months, except for the few glasses of beer in July, until about 10 days previous to this visit, when he had resumed drinking and had continued it for 7 days. During this time he omitted amphetamine sulfate. However, 4 days before he had stopped drinking and resumed the medication, and he felt that the episode was over.

In more than 16 months since beginning treatment this patient had had two episodes of heavy drinking, each lasting less than a week and 7 months apart. In addition he had had two periods of 'social drinking', one lasting less than a week and limited to beer, and the other occurring during a cruise and largely limited to beer. Except for these four episodes he had had nothing what ever to drink. In other words, he had been helped so far as his day-to-day drinking is concerned.

**Case 2** The patient, a 32-year-old salesman, was first seen on July 8, 1937. He had been drinking heavily for 15 years. In the last few years, two or three times a week he had been starting to drink in the morning, and continuing throughout the day and evening, neglecting his business and his home. The episodes had been increasing in frequency.

He was started on amphetamine sulfate, 20 mg daily. On July 27 he reported that he had not had anything to drink and had had no impulse to drink. However, this was his last visit. A report from his relatives at a later date stated that he had stopped drinking for 2 or 3 months but had then begun it again.

**Case 3** The patient, a 50-year-old real estate broker, was first seen on September 22, 1937. He had been drink-

ing for 26 years, but had begun to drink heavily in the last 8 years, after his business had collapsed in the financial depression. In the past 2 years his drinking had interfered with his business and his home life. His usual course was a drinking bout lasting about a week, during which time he did not go home, but took a room in a hotel and drank gin in large quantities. These bouts usually came at intervals of 1 to 3 weeks. His longest free period in the previous 2 years had been 3 weeks, except for the 5 weeks previous to his visit, 3 weeks of this time, however, had been spent in bed with measles. He had previously been treated by psychotherapy, with no effect.

He was started on amphetamine sulfate, 20 mg daily. At the time of his last visit, on October 6, 1938, he had not had a drink of any kind since his first visit, almost 13 months before. He was still taking amphetamine sulfate, 40 mg daily. He had had no temptation to drink, in spite of the facts that his business was still in very poor condition and his domestic financial situation quite trying and that he had undergone an appendectomy, suffered the collapse of a financial scheme, and had disappointments as the captain of a squash team at his local club. He reported that during this time he had frequently been to parties where everybody else was intoxicated, but had not taken a drink.

**Case 4** The patient, a 42-year-old housewife, was first seen on September 23, 1937. She had been drinking heavily for 10 years. She drank daily, and her husband reported that she was quite constantly under the influence of alcohol. In the previous 2 years she had been for 14 months in an institution, and the early part of this time had been the only free interval in the last 5 years. Even during the latter part of her stay in the institution she drank whenever she was allowed out on parole, even on 1-day visits to town for shopping. In the 3 weeks preceding her first visit to me, her longest free interval had been 3 days.

She was put on amphetamine sulfate, 20 mg daily, and the dose was soon raised to 40 mg. For 3 weeks she continued to drink to some extent daily, although according to reports from her family the amount consumed was less than it had been. On October 15 she stopped drinking and continuing to take amphetamine sulfate went for over 2 months without drinking, except for a glass of beer on two social occasions. On December 19 she started a 3-day episode of drinking beer. During the first week of January, 1938, she again drank beer, and this time also some wine. Beginning with January 8, 1938, she went for 2½ months without drinking, except for a very rare glass of beer. On March 23 her husband, without any warning, failed to come home to dinner. She began to drink whiskey quite heavily, and continued this until April 3. She then resumed amphetamine sulfate, 40 mg daily, and went for 3½ months without any drink, not even beer. In the middle of July she again began to drink heavily, fell and broke her ankle. She took a good deal of sedative, and when seen on July 20, 1938, was suffering from acute Amytal intoxication. She was sent to a hospital and given amphetamine sulfate, and was discharged a week later, apparently recovered. The patient has not reported since that time, but on October 23 her husband stated that she had been drinking more or less steadily since her discharge from the hospital, although not so heavily as usual.

**Case 5** The patient, a 30-year-old clerk, was first seen on October 22, 1937, on the verge of delirium tremens. He

chotherapy Obviously, when such a patient talks freely this has a certain psychotherapeutic value, but no attempt at interpretation was made, and no advice was given as to organization of patients' lives or problems All the patients remained ambulatory None were confined to institutions as a part of their treatment

At the first interview, it was explained to the patient that alcoholism was a disease, and that the mere knowledge that one ought not to drink was not usually sufficient to cure it It was stressed that unless the patient *wanted* to stop drinking no one could help him, but that if he did want to the medication given would probably be of assistance in bolstering his purpose The patients were told that there was no trick or magic about the medicine, but that it was better for them not to know—at first, at least—what drug they were taking, so that they would not be influenced by anything they might hear or read in newspapers about it\*

With this preliminary, the patients were given a supply of 10-mg tablets of amphetamine sulfate and instructed to take two tablets daily, one immediately on arising and one at noon They were told that the dose might need to be adjusted, and were instructed to return in one week

Each patient was seen at weekly intervals for several weeks, then, if all went well, at two-week intervals and later once a month The patients who have been longest under treatment now report once in two or three months Doses were increased in several cases, and decreased in 1 Several patients were instructed in the course of their treatment to take an additional tablet in the late afternoon whenever they expected to be out in the evening at a place where drinking would be going on They were not asked to avoid parties, or in any fashion to modify their way of living, except as such modification developed naturally and spontaneously during their treatment

#### UNTOWARD EFFECTS

Only 1 patient (Case 14) found that the usual dose made him "jittery" and nervous and unable to sleep, he was so alarmed that he telephoned for advice He was advised to take a smaller dose and subsequently had no untoward effects In no case was there any disturbing effect Insomnia occurred infrequently, and was transient There was no marked loss in weight, no increased nervousness, no loss of appetite, no rise in blood pressure and indeed no other unpleasant accompaniment

There has been no evidence whatsoever of ad-

diction or habit formation Several patients spontaneously suggested omitting the pills, and a few actually did so without being told None have given any sign, consciously or unconsciously, of a need to continue the drug, such as would be present if a habit had been formed or a true addiction had occurred

#### RESULTS

In all, 21 cases were treated, including 4 seen by Dr Marjorie Meehan, of Princeton, New Jersey, at my suggestion I am greatly indebted to Dr Meehan for permission to include these cases here

In 5 of my cases and 3 of Dr Meehan's, the patients took no alcohol in any form after beginning treatment, at the present time, these periods of abstinence vary from two weeks to thirteen months, and are more than four months in 6 cases In 14 cases of the entire series the results may be considered reasonably successful either the patients abstained entirely, or their drinking habits were so modified that they were able, by and large, to resume their places in the family and business world, even though they suffered one or two lapses from total abstinence In only 4 cases (Cases 2, 7, 15 and 16) was there total failure, and even in 3 of these there was a short period of abstinence In all the others there was a period of abstinence significantly longer than any free interval in the year or two preceding treatment

Evaluating the results in another way and estimating the length of abstinence under amphetamine sulfate as compared with pre-treatment abstinence, we find that in 15 of the 21 cases the abstinence period was at least six times as long as the usual free interval before treatment (not counting, of course, those free intervals which were due to hospitalization) Of the remaining 6 cases, 3 (Cases 14, 17 and 21) have remained completely abstinent, but have not yet been under treatment for as long as six times their pre-treatment free interval

It has been stated by most patients whose treatment can be called successful that they have no desire to drink They feel alert, energetic and able to do their work and face their difficulties They say that they no longer need the support of alcohol, and consequently have no temptation to drink

#### CASE REPORTS

*Case 1* The patient, a 45 year-old man, a retired executive, was first seen on June 29, 1937 He had been drinking heavily for over 12 years During this time he had been treated at most of the sanitariums and hospitals of New England, and was known to many psychiatrists In the previous year his longest free period—one without a

\*This work was begun at about the time when amphetamine sulfate was receiving a good deal of undeserved and unfavorable publicity as pep

*Case 11* The patient, a 40-year-old broker, was first seen on May 10, 1938. In recent years he had drunk  $\frac{1}{2}$  to 1 quart of whiskey daily, with the longest free interval 2 or 3 days, except for one period of about 6 months ending  $2\frac{1}{2}$  months before his visit, and including a time when he had been sentenced to the State Farm as a common drunk at the instance of his family.

The patient was put on amphetamine sulfate, 20 mg daily. On September 29 he reported that he had had no alcohol whatever, except one glass of beer on a very hot day in July, when he had no desire to take any more. He felt more energetic and got a great deal of work done, both in his business and in physical labor around his house. He had been to two college reunions and one high school reunion, all of which he characterized as drunken brawls, but had not had anything to drink at any of them. Even the serious illness and death of his father, who had been found to have a carcinoma about 2 months before, had not tempted him to resume drinking.

*Case 12* The patient, a 33-year-old housewife separated from her husband and unemployed, was first seen on May 16, 1938. She had been drinking heavily for 3 years. She drank gin or whiskey, about 1 pint daily, and had had a drink every day for the past 6 months, with an excessive bout about 1 month previously. She drank because she became depressed. She had not had a drink for 2 weeks.

She was started on amphetamine sulfate, 20 mg daily. On June 20 she reported that she had had nothing to drink except for two glasses of beer about 3 weeks before. She felt well, and much encouraged about her domestic situation. She had taken up to 40 mg of the drug daily, but was then down to 10 or 15 mg. She has not returned for a further interview.

*Case 13* The patient, a 42-year-old unemployed insurance broker, was first seen on May 16, 1938. He had been drinking heavily for 18 years. His drinking episodes lasted for 2 or 3 weeks and occurred at intervals of 6 or 7 weeks. During sprees he drank about a quart of whiskey a day. He had been discharged from the Boston City Hospital 10 days previously, after recovery from an attack of delirium tremens.

He was put on amphetamine sulfate, 20 mg daily. On October 17, when last seen, he had not had a drink for  $5\frac{1}{2}$  months and felt that he had beaten his problem, since his longest free interval in many years before starting treatment had been 8 weeks. He was working on the WPA, was enjoying his work and felt well. He was taking 30 mg of amphetamine sulfate daily.

*Case 14* The patient, a 30-year-old unemployed man, was seen first on May 24, 1938. He had been drinking for 15 years, heavily in the last 4 or 5 years. He had gone on sprees lasting for 3 weeks every 2 or 3 months, and averaged  $1\frac{1}{2}$  quarts of whiskey per day during them. In the last 2 years his longest free interval had been 3 months. He had had his last drink about 1 month before, after a 3-week drinking bout.

The patient was put on amphetamine sulfate, 20 mg daily, and showed an apparent susceptibility to the drug. Two days after he started treatment he was called to his home during the night. The pills had made him nervous, so he had taken more of them. He had had about 150 mg in the 2 days, was unable to sleep and was trembling, pale and clammy. The drug was discontinued and he recovered within 36 hours. He was put on daily doses of 10 or 15 mg.

When seen on September 19 he said that he had not had anything to drink for over 5 months. He had been

somewhat erratic in taking the drug since he had found that a full dose caused insomnia. On the day of this visit he felt that he wanted a drink for the first time but had fought it off. He had not been taking amphetamine sulfate in the preceding 2 weeks.

On November 3 he reported that the drug taken on September 19 had tided him over his temptation and that he subsequently had not had a drink. He had been working fairly regularly.

*Case 15* The patient, a 32-year-old WPA truck driver, was first seen on August 1, 1938. He had been drinking heavily for 10 years, usually over each week end, consuming a quart of whiskey and a good deal of beer on each occasion. His longest free interval in the past year had been 2 weeks. His longest free interval in the last several years had been 3 months, in 1935.

He was put on amphetamine sulfate, 20 mg daily.

He has not returned. His wife reported on October 15 that he took one pill in the morning for about 3 weeks, and 4 days after beginning the treatment developed insomnia, he drank about once a week, but not heavily. At the end of this period he stopped taking the drug and went on a prolonged alcoholic spree. Since then he had been drinking about as heavily as usual.

*Case 16* The patient, a 26-year-old man, was first seen on August 1, 1938. He had been drinking heavily for many years, taking 1 to 2 quarts of whiskey daily, in sprees lasting several weeks and occurring every few months. At the time of this visit he had not had a drink for 10 days, but before that had been drinking steadily for 5 weeks, after a free period of 2 months.

He was put on amphetamine sulfate, 20 mg daily. On August 22 he reported that he had drunk nothing and had had no desire to drink. He felt extremely well. On November 3 his foster mother reported that for 1 month after starting treatment the patient had stopped drinking. Then he had begun to drink erratically and refused to take any more amphetamine sulfate.

*Case 17* The patient, a 38-year-old chauffeur, was first seen on September 13, 1938. He had been drinking heavily for many years. He drank gin, whiskey or pure grain alcohol, usually in a bout lasting 2 weeks and occurring every 2 months, he averaged 2 quarts daily during the bouts. He was obviously drunk when seen.

He was put on amphetamine sulfate, 20 mg daily. On September 21 he reported that, apparently because under the influence of alcohol when he received his instructions, he had misunderstood them, and had taken about fifteen pills (150 mg) the day after his visit in trying to get over his shakiness, supposing that the medicine was a sedative. His heart began to pound, a pulse beat in his stomach and he did not sleep that night, but there were apparently no other ill effects, and by the next morning even these vascular effects were gone, although he felt nervous and shaky. He had taken all his pills except one, so that he had none to take during the rest of the interval between visits. On the 4th day after the first visit he had had two drinks but no other alcohol. The terms of dosage were made clear to him. On October 7 he reported having drunk no alcohol since the last visit, except for a glass or two of vermouth at a party. He was taking 20 mg of amphetamine sulfate daily, with another 10 mg in the evening twice each week. He believed that he would be drinking if it were not for the pills—he still wanted to drink, but the pills helped him fight off the desire. He felt that the morning pill quieted him. He said that his internal tension was relaxed. He was working and ate and slept well.

had been drinking for 10 years or more, and quite heavily for the preceding 2 years. He drank beer and whiskey. In the previous 6 months he had been drinking heavily and almost continuously, with the longest free interval 6 days. Before this period, however, he had gone for 5½ months without a drink.

He was put on amphetamine sulfate, 20 mg daily, and for 2 weeks stopped drinking. He failed to report for the next 3 months. On February 8, 1938, he reported that he had been drinking heavily, almost since his last visit. He had taken no pills during this period. He again was very nervous and fearful.

The patient was again put on amphetamine sulfate, but did not return until 4 months later, when he drifted into the outpatient department of a Boston hospital. He was examined, recognized as my patient and returned to me. He was again fearful and nervous and on the verge of delirium. He said he had taken the pills for 3 weeks after his previous visit, and had not had a drink for 2½ months, but had then begun again.

He was again put on amphetamine sulfate. On August 4 he reported that he had gone for 6 weeks without a drink, except for some beer on a very hot evening a few days before, and that he still continued to take amphetamine sulfate. He has not reported since, but on October 20, 1938, his mother stated that he had not had a drink for many months and was working regularly. She said he had not been taking the pills recently.

**Case 6** The patient, a 40-year-old housewife, was first seen on November 16, 1937. She had been drinking for 5 years, usually on sprees lasting 2 or 3 weeks and recurring every 3 months. In the past year her husband had been ill and her son had been sent to prison. She was on the verge of delirium tremens.

She was started immediately on amphetamine sulfate, 20 mg daily. On December 16 she reported that she had had nothing to drink since the treatment was started. She was told to take the pills only on those days when she felt discouraged or that she might want a drink.

On October 13, 1938, 11 months after beginning treatment, the patient's husband reported that she had gone for 9 months without a drink. In the previous 2 months, however, he said that there had been two drinking episodes. She had not taken amphetamine sulfate for several months.

**Case 7** The patient, a 58-year-old retired business man, was first seen on January 4, 1938. He had taken alcohol for 40 years. In the previous 4 years, since his wife's death and since his daughter had left him, he had been drinking heavily. He drank whiskey, and averaged 10 ounces a day, with 16 ounces on heavy days and 6 ounces on light ones. There were no free days. All available forms of treatment had been tried without success.

The patient was put on amphetamine sulfate, 50 mg daily. He has never returned. Two weeks after his visit he reported by telephone that the pills helped somewhat but that he had not stopped drinking.

**Case 8** The patient, a 63-year-old business man, was first seen on January 31, 1938. He had been drinking heavily during the previous 5 years, he drank gin, in sprees lasting several days and occurring every 2 or 3 weeks. He thought that his bouts began when he was lonely or depressed. His drinking became worse when his wife died and his sons left him alone in his home.

The patient was put on amphetamine sulfate, 20 mg daily. He went for 3½ months without a drink, and one of his sons reported that he was greatly improved in every respect and had renewed some of his old interests and

friendships. On May 24 he reported that a month or 6 weeks previously he had felt so much better and so confident that he had stopped taking the pills. Several weeks before this visit he had pulled a muscle in his back. This was very painful, but neither his son nor his physician appreciated how painful it was, and were not very sympathetic. As a result, according to him, he had begun drinking a week before his visit. Amphetamine sulfate was started again, and he continued without a drink through a European tour.

On October 21 his son reported that he had again stopped taking the pills. A month previously, after the New England hurricane had blown down most of his trees, he had had another drinking episode lasting 2 or 3 days, but had then stopped and resumed medication. The son added that his father occasionally had a drink when he came to town to visit, but did not get drunk and did not continue his drinking on the following day.

**Case 9** The patient, a 44-year-old insurance broker, was first seen on March 9, 1938. He had been suffering for many months from a parotid tumor, but was so fearful that he could not bring himself to consult a physician about it. Finally he went to a surgeon, who recommended operation, but because he was drunk and had been drinking heavily for some time and because the tumor was obviously a benign one, he was referred to me for preliminary treatment.

The patient had been drinking heavily for many years. For the previous 3 or 4 years he had been drinking 1½ to 2 quarts of whiskey per day quite regularly. He admitted having had many hypochondriacal ideas, and said that he had begun drinking heavily in an attempt to overcome these various pains and aches. He was depressed and fearful.

He was put on amphetamine sulfate, 20 mg daily, and on March 16 this dose was increased to 40 mg. On April 20 he reported that he had had only one highball since starting treatment, and that in the 1st week. He had been drinking a glass or two of sherry every day, but had had nothing stronger, nor had he been at all intoxicated since beginning treatment.

On May 2, 1938, the parotid tumor was excised. The patient has not since returned, but on October 26 his mother reported that he was getting along very well, and so far as she could tell he was not drinking. She said that she did not know whether he was continuing to take the drug.

**Case 10** The patient, a 40-year-old housewife, was first seen on March 15, 1938. She had been in a serious automobile accident 4 years before, when the person sitting beside her was killed, and had since suffered from phobias and an anxiety state. She had begun to drink in an effort to overcome these, and had been drinking steadily and heavily. She had been taking about a pint of gin a day, with no free days until a week before her visit, when she had become tremulous and terrified, and had heard voices for an hour. She had had no alcohol since that time. When seen she was on the verge of delirium tremens, and in addition, tenderness of the muscles and weakness suggested an early peripheral neuritis.

She was put on amphetamine sulfate, 20 mg daily, and on adequate treatment for her vitamin deficiency. She stopped drinking entirely. On August 15 the patient's physician reported that she had had nothing to drink until about August 1, a period of 4½ months, she had then drunk for a short time, after an acute financial crisis, but had stopped drinking after a few days. She later reported that the fears seemed lighter and easier to bear when she was taking the drug.

portant. Because of the experimental aspect of this study, no attempt has been made to take advantage of the situation. However, it is my belief that the greatest benefit from the use of amphetamine sulfate in alcoholics will arise out of this circumstance. The free interval which amphetamine sulfate appears able to produce should allow time for the institution of more fundamental psychotherapeutic approaches. Probably the real value of the treatment will prove to be just this opportunity to inaugurate psychotherapy on a basis of good rapport and confidence and sobriety, so that the gain made by the treatment may be consolidated by more fundamental modifications of the alcoholic's personality and his attitude toward life.

One or two of the patients in this series, in common with many other chronic alcoholics, have been addicted to barbituric acid compounds, and amphetamine sulfate has been of help to them in this respect. In addition, certain experiences with amphetamine sulfate in acute drug comas have been suggestive. It appears that another valuable use of the drug may well prove to be in the treatment of drug addictions, including both the barbiturates and the morphine derivatives, and studies of its value in these cases should be undertaken.

#### SUMMARY

A method for treating chronic alcoholism with amphetamine (Benzedrine) sulfate is presented.

Reports of 21 cases so treated are given.

It is concluded that the method is of great value in the treatment of chronic alcoholism.

It is suggested that the use of amphetamine sulfate may permit a sufficient interval of sobriety for the institution of the usual and more fundamental psychotherapeutic methods.

It is pointed out that amphetamine sulfate may be useful in the treatment of drug addictions, and its employment therein should be investigated.

189 Bay State Road.

The following 4 cases were treated by Dr Meehan

*Case 18* The patient, a 43-year-old man, had been drinking fairly heavily since the age of 17. Before Prohibition he frequently took a pint of whiskey before breakfast. Nevertheless, his drinking did not interfere with his work and he was successful as a skilled mechanic until the age of 39. At this time he began to become intoxicated more frequently. He lost much time from work, was abusive to his wife, harsh to his children and neglectful of home responsibilities. He was arrested for drunkenness several times, and was finally sent to a state hospital in April, 1937. He apparently showed no signs of alcoholic psychosis, however. He remained in the hospital for 6 weeks. After discharge he remained sober for a few months and then began drinking more heavily than ever. He was returned to the state hospital in December, 1937, and remained there until March, 1938. On discharge he immediately resumed drinking to excess.

He was first seen May 25, 1938, at the requests of a social worker and of his wife. At this time he was markedly intoxicated and thoroughly unco-operative. A few days later he was persuaded to try amphetamine sulfate 10 mg twice daily. He stopped drinking immediately. His disposition improved. Whereas formerly he had taken no interest in the home, he began to repair the furniture, help his wife with her work and volunteer to do errands. He said that he felt better than he had ever felt before. After taking 20 mg daily for about 3 weeks he began to notice occasional nausea. At this time the dose was reduced to 10 mg daily, before breakfast. He continued this for 2 weeks longer, during which time his condition continued excellent. He then discontinued the medicine entirely. On September 23 he said that he had not taken any amphetamine sulfate or other medication since early July, but had had no desire to drink. The change in his personality had continued, and both he and his wife agreed that his condition could not have been better.

While taking the amphetamine sulfate the patient not only had no desire to drink, but the sight or smell of alcoholic liquor was extremely disgusting to him. Since discontinuing the medication, he no longer experienced this disgust, but merely had no interest in or desire for alcohol.

*Case 19* The patient, a 43-year-old woman, was the wife of the patient in Case 18. When she married at the age of 20 she was at first disgusted by her husband's drinking. Gradually, however, she began to drink with him. This did not become serious until she had reached the age of 38 or 39, when husband and wife both began to drink very heavily. The children were frequently neglected, and on several occasions the police intervened. The patient insisted that she only drank to keep her husband company and to find relief for her worry about his drinking, and never really enjoyed it. However, she finally was sent to a state hospital in December, 1937, and remained there until April, 1938, without apparent psychotic symptoms. On discharge from the hospital she started drinking again. The two children had been placed in an institution during the hospitalization of the parents. When the mother returned from the hospital she took the 12-year-old boy back to live with her and her husband in furnished rooms, but gave him relatively little attention. She refused to take the 2 year-old child.

She was first seen May 25, 1938. At this time she was sober but extremely tense. She was pale and trembling. She was eager to try any treatment, and enthusiastically

welcomed the suggestion of taking amphetamine sulfate, 10 mg twice daily. She continued this for 3 weeks and then reduced the dose to 10 mg before breakfast, 2 weeks later she discontinued the medication entirely. On September 23 she reported that she had had no alcohol and no desire for it since beginning treatment. She had re-established her home with both children and was taking excellent care of house and family. She said she felt very well.

*Case 20* The patient, a 47-year-old Negro, had been drinking heavily all his life. It was impossible to find out what quantity he had taken, but he had been known as one of the worst drunkards in town. He worked irregularly and spent whatever he earned on liquor. He came only at the insistence of his wife, who threatened to leave him unless he took treatment, and had no expectation of being helped.

On June 24, 1938, he began taking amphetamine sulfate, 10 mg twice daily. He reported 1 week later that he had been taking the tablets regularly and felt better than he had for years. Whereas formerly he was occasionally short of breath in the mornings, this symptom had now completely disappeared. He had not had any wine or whiskey to drink and had had no desire for them. However, he had had several cans of ale, which he enjoyed. His wife reported that he had not been intoxicated, that he had brought money home for the first time in years, and that he was much pleasanter to her and his two sons than he had been previously. However, she noted that he was more restless than before and wanted to be constantly active. He continued taking 20 mg of amphetamine sulfate daily until early September, when on two occasions he had momentary dizzy spells. The dose was reduced to 10 mg daily, and up to September 22 he had had no more spells. He drank three or four cans of beer or ale a week, but no wine or whiskey, and had not been drunk.

*Case 21* The patient, a Negro, was referred by police. He had been drinking in moderate amounts since childhood. In recent years the craving had increased and intoxication was more frequent. He was eager to be cured. On August 31, 1938, he began taking amphetamine sulfate, 10 mg twice daily. Desire for drink stopped immediately. He had been taking ale occasionally but was satisfied by one glass. His wife has reported that he had not been drunk and his disposition had improved remarkably. On September 12 the dose was reduced to 10 mg before breakfast and 5 mg before lunch.

#### COMMENT

It would be over-sanguine to assume that amphetamine sulfate can alone solve the problem of alcoholism. In almost all the cases in this series the patients have gone through a more or less prolonged period of greater accessibility, due to their sobriety. If one assumes that the patients in this group who have been most successful represent those who were really anxious to stop drinking, but had been unable to do so without external assistance, the improved rapport between patient and psychiatrist is understandable, when the patients find that they have actually been able to stop drinking. The fact that this has been accomplished without hospitalization is also quite im-

**Revolution** In varying degrees, perhaps least of all in religious life, the career of the humanitarian student has become inseparably linked with the financial and industrial domination of the present era. Nowhere, however, is this loss of material and economic simplicity more in evidence than in the discipline of science—an inevitable occurrence, of course, since scientific discoveries themselves had so much to do with making possible the Industrial Revolution.

Scientific study and practice have been profoundly affected by modern materialism in two ways. The first is that even in the pursuit of pure scientific knowledge, guided by the highest ideals of natural philosophy, the average student is helpless without the aid of costly and elaborate equipment. The second and more important effect is that the entrepreneur class has subsidized scientific endeavor, to the end that the entirely modern study of applied science has been created largely to meet the needs of industry.

Applied science, from the standpoint of men, money and materials, dominates scientific education today. It capitalizes when necessary the principles of natural philosophy, but it shuns that ancient discipline's academic tradition of the pursuit of knowledge for its own sake. Frankly and unashamedly commercial, dominated by the entrepreneur spirit, it attracts its numerous students because of the distant promise of highly paid industrial positions. The prototype of the average scientific student of today is not, as may be popularly supposed, Leonardo da Vinci or Galileo, but rather the skilled artisan and the guildmaster of the machineless past.

The scientific method has been irrevocably appropriated by artisans and merchants as a means of profit, and from this action have resulted numerous material blessings, but as with any unfinished scientific experiment, the whole matter does not yet permit unqualified praise or condemnation. This much is certain, that with education pointing the way we must strike a compromise in order to ensure the continuance of worldly progress as the servant and not the master of the high mortality inherent in the cultural discipline which made it possible.

In no field of scientific endeavor is the necessity for such a compromise more clearly indicated than in medical science. Our failure here to bring progress under the control of an older and wiser cultural tradition cannot be otherwise than fatal to the successful continuance of an institution founded on the ideals of service and truth.

That part of modern scientific medicine which is represented by the training and practice of physicians bears a peculiar relation to the develop-

mental changes in the rest of cultural learning that have been discussed. We find here a professional group which, in theory at least, exists for the primary purpose of fulfilling a rigorous set of moral obligations which have remained unchanged throughout the centuries. Under present-day conditions, however, in order that it may perform its function efficiently the medical profession is forced to depend heavily upon the services of the practical scientist and the entrepreneur. From these two come the costly and intricate instruments, the methods of organization and mass production, the endowments and capital and the maintenance of a large lay personnel, which in conjunction with traditional medicine have brought into being the most complete and extensive system of medical care ever known. Expressed in another way, the skilled craftsman and the business man have invaded an ancient branch of natural philosophy, and have made possible one of the most dramatic civilizing contributions that the world has seen.

The brilliance of this achievement should not blind us to the danger inherent in a system of medical care that entrusts so much of its vital functioning to agencies which admittedly work for selfish and materialistic purposes. Sir William Osler recognized this danger when he wrote, "Great material prosperity has weakened the influence of ideals and blurred the eternal difference between means and end." That which Osler had the foresight to fear a generation ago is even more apparent today. If we examine in detail the economic aspects of the development of modern medicine, we shall find factual proof that before the sheer weight of dollars and man-power, medical men are in a vulnerable position in so far as their capability of maintaining the directional control of their science is concerned.

The physical instruments and the economics of medical care, as might be inferred from what has been said of early natural science, were once of a very primitive type. Of the total amount of money formerly required for medical purposes, by far the greatest proportion was paid for intangibles—service and advice. The cost of drugs no doubt figured significantly, but to no greater extent than it does today. The cash value of instruments was negligible. Hospitals were few. Dentistry such as we now have was unknown. There was no true profession of nursing, friends and relatives performed this task gratuitously. There was no public-health work to speak of, and what did exist included no preventive medicine. From these facts we conclude that in days gone by, practically every penny of each dollar of medical purchasing power was paid to physicians in pri-

## THE CONTROL OF MEDICAL SCIENCE \*

MICHAEL V. MacKENZIE, M.D.

LONDON

EVERY historical period has its false prophecies, its specious beliefs and its ignoble ideas which when followed long enough may destroy individuals, classes, nations or even entire civilizations. Twentieth-century America is no exception. Here we find that by a special combination of historical circumstances, a certain erroneous belief has become more prevalent than ever before in the history of the world. This false doctrine is that the perfection of the individual or the social group or its cultural standards can be measured in terms of material prosperity. America has made a cult of applied science, and her people worship the high priests of practical invention, industry and finance. More smugly even than the Pharaohs gazing at their pyramids, we Americans look upon our skyscrapers, our automobiles and our gadgets and acclaim the peak of civilization. As completely as did any handful of gilded nobility in the past, we neglect great moral truths—those specific attributes of civilized man which invariably determine the historical destiny of individuals, race and nation.

The moral fiber of a civilization, composed of its ethical standards, its social justice, its tolerance, its achievements in pure science and the arts, is preserved by its educational system. Teaching may take the form of the pronouncements of a patriarch across a desert campfire, or of innumerable weighty lectures delivered at a great center of learning. No matter what the external guise, however, education fulfills its role as the perpetuator of cultural standards only to the extent that it presents disciplines. Of these, four are of outstanding importance: theology, jurisprudence, literature and natural science. When we recall the perfection of the Golden Age of Greece, we can appreciate that to teach a philosophy of life and a rational legal code and aesthetics and to stimulate an intelligent curiosity about natural phenomena will bring glory to the human race in the absence of the superadded features of modern education.

The four cardinal disciplines referred to exemplify purely cultural learning. Throughout their history they have had much in common, and even today, beneath our technocratic exterior, they are firmly united as the backbone of education. Yet in recent times they have begun to lose in

varying degrees one of their formerly outstanding mutual characteristics. This is the physical simplicity by which all forms of cultural learning were once required and practiced. I do not mean by this that their actual indoctrination was intellectually an easy task. I refer to the fact that law, philosophy, science and religion could be taught and applied without the use of tools and instruments. When Jesus instructed His followers "For where there are two or three gathered together in my name, there am I in the midst of them," he stressed the simplicity of religious practice, but such was also the pattern of all other cultural endeavor. A teacher, disciples, a few authoritative writings and the world of observable nature were the only requisites for work in theology, law, literature and science. A bible and a congregation sufficed for the man of God, codes and precedents for the jurist. The literary man needed only a library and writing materials, and the natural scientist—also the physician of those days—depended more upon the acuity of his own senses than upon his few rough tools.

We may attach considerable importance to this independence of cultural learning of material instruments, for the reason that it had the indirect effect of creating a sharp distinction between scholarly endeavor and commercial acquisitiveness. There was no reason why the financial affairs of men of learning should be more involved than those of the most primitive kind of merchant. Their professional overhead was low. Priest, lawyer, physician and author spent relatively small sums for education and for professional maintenance. In a sense they were public employees who received fees, taxes or tithes in return for which they gave neither product nor merchandise, but an entirely intellectual type of service. This unsophisticated economic relation between the professions and the buying public was not the commercial one which exists today between producers and consumers. Although money changed hands, practically none of it represented capital goods or consumers' goods. The only merchandise was intangible, consisting of ideas, advice, theories and guidance.

Now, it would indeed be remarkable if these simple economic affairs of what we may call the professional class failed to be affected by the tremendous changes arising out of the Industrial

**Revolution** In varying degrees, perhaps least of all in religious life, the career of the humanitarian student has become inseparably linked with the financial and industrial domination of the present era. Nowhere, however, is this loss of material and economic simplicity more in evidence than in the discipline of science—an inevitable occurrence, of course, since scientific discoveries themselves had so much to do with making possible the Industrial Revolution.

Scientific study and practice have been profoundly affected by modern materialism in two ways. The first is that even in the pursuit of pure scientific knowledge, guided by the highest ideals of natural philosophy, the average student is helpless without the aid of costly and elaborate equipment. The second and more important effect is that the entrepreneur class has subsidized scientific endeavor, to the end that the entirely modern study of applied science has been created largely to meet the needs of industry.

Applied science, from the standpoint of men, money and materials, dominates scientific education today. It capitalizes when necessary the principles of natural philosophy, but it shuns that ancient discipline's academic tradition of the pursuit of knowledge for its own sake. Frankly and unashamedly commercial, dominated by the entrepreneur spirit, it attracts its numerous students because of the distant promise of highly paid industrial positions. The prototype of the average scientific student of today is not, as may be popularly supposed, Leonardo da Vinci or Galileo, but rather the skilled artisan and the guildmaster of the machineless past.

The scientific method has been irrevocably appropriated by artisans and merchants as a means of profit, and from this action have resulted numerous material blessings, but as with any unfinished scientific experiment, the whole matter does not yet permit unqualified praise or condemnation. This much is certain, that with education pointing the way we must strike a compromise in order to ensure the continuance of worldly progress as the servant and not the master of the high mortality inherent in the cultural discipline which made it possible.

In no field of scientific endeavor is the necessity for such a compromise more clearly indicated than in medical science. Our failure here to bring progress under the control of an older and wiser cultural tradition cannot be otherwise than fatal to the successful continuance of an institution founded on the ideals of service and truth.

That part of modern scientific medicine which is represented by the training and practice of physicians bears a peculiar relation to the develop-

mental changes in the rest of cultural learning that have been discussed. We find here a professional group which, in theory at least, exists for the primary purpose of fulfilling a rigorous set of moral obligations which have remained unchanged throughout the centuries. Under present-day conditions, however, in order that it may perform its function efficiently the medical profession is forced to depend heavily upon the services of the practical scientist and the entrepreneur. From these two come the costly and intricate instruments, the methods of organization and mass production, the endowments and capital and the maintenance of a large lay personnel, which in conjunction with traditional medicine have brought into being the most complete and extensive system of medical care ever known. Expressed in another way, the skilled craftsman and the business man have invaded an ancient branch of natural philosophy, and have made possible one of the most dramatic civilizing contributions that the world has seen.

The brilliance of this achievement should not blind us to the danger inherent in a system of medical care that entrusts so much of its vital functioning to agencies which admittedly work for selfish and materialistic purposes. Sir William Osler recognized this danger when he wrote, "Great material prosperity has weakened the influence of ideals and blurred the eternal difference between means and end." That which Osler had the foresight to fear a generation ago is even more apparent today. If we examine in detail the economic aspects of the development of modern medicine, we shall find factual proof that before the sheer weight of dollars and man-power, medical men are in a vulnerable position in so far as their capability of maintaining the directional control of their science is concerned.

The physical instruments and the economics of medical care, as might be inferred from what has been said of early natural science, were once of a very primitive type. Of the total amount of money formerly required for medical purposes, by far the greatest proportion was paid for intangibles—service and advice. The cost of drugs no doubt figured significantly, but to no greater extent than it does today. The cash value of instruments was negligible. Hospitals were few. Dentistry such as we now have was unknown. There was no true profession of nursing, friends and relatives performed this task gratuitously. There was no public-health work to speak of, and what did exist included no preventive medicine. From these facts we conclude that in days gone by, practically every penny of each dollar of medical purchasing power was paid to physicians in pri-

vate practice. They in turn used this income almost entirely for personal ends, requiring only a small amount for professional overhead expenses.

Under modern conditions, medical science has become much more comprehensive, and is no longer synonymous with the activities of the handful of men comprising the regular medical profession. Of all the persons engaged in supplying the medical needs of this country, only one in nine is a licensed physician—a ratio which would be even lower if the total included the employees engaged in selling and manufacturing drugs and instruments. This huge auxiliary army of medical workers and the institutions which it represents absorb about 70 per cent of the money spent annually for medical purposes. The remaining 30 per cent represents the gross amount paid to physicians in private practice, of which an unestimated but indubitably large proportion is in turn required for overhead expenses, and is thus added to the 70 per cent just mentioned.

The traditional belief that the practicing physician is the central and controlling figure in our system of medical care is taken for granted by medical men and approved by the majority of the general public. Neither appear to realize, as is clear from the statistics just quoted, how tenuous is the arithmetical basis upon which the supposed hegemony of the regular medical profession is founded. Representing about a tenth of the manpower and less than a third of the financial power concerned in the administration of medical care, physicians will require vastly more legal and regulatory authority than they now have if they are to continue to control medicine in fact as well as in theory.

Now, the 70 per cent of the medical budget not destined for practicing physicians is subdivided as follows: hospital facilities, 23 per cent, drugs (including patent medicine), instruments and miscellaneous, 20 per cent, dental care, 12 per cent, irregular practitioners, cultists, quacks, and so forth, 7 per cent, nursing care, 5 per cent, and public-health work, 3 per cent. That a considerable part of this money is now being spent as wisely and efficiently as it could be under any other system of medical care is unquestioned, it is equally true that its allocation is partially approved, even if not actually controlled, by the medical profession. By far the larger amount, however, is in the hands of lay people. Many of these, flagrantly contradicting the medical profession's own ideal of service, profit by the needs of universities, physicians and patients for medicines, instruments and laboratory equipment, selling this necessary material on the commercial basis of

charging all that the traffic will bear. Real estate, automobiles and building materials—as vital to modern medicine as is scientific equipment—are rarely acquired without some “humanitarian” realizing his 5 to 20 per cent margin of profit. Despite the physicians' avowed influence in hospital affairs, politicians, trustees and unpredictable dispensers of charity too often have actual control of the working of these institutions. A notorious evil, of course, is the relentless grasp of the politician upon the public-health work of many states and municipalities.

Nowhere, however, is the misdirection and tragic wastefulness of precious medical funds more glaringly revealed than in the profitable patent-medicine trade and the activities of irregular practitioners. The palpable charlatan and the vendor of cheap nostrums to the ignorant poor have been parasites on medical science for centuries, but our streamlined industrialized society makes possible an ultrasophisticated brand of knavery that befuddles university presidents and often misleads the medical profession. Protected by the dawdling of legislators and the inadequacy of existing federal laws, capitalizing the popular prevalence of an inaccurate scientific terminology, aided by the great majority of drugstore proprietors and by a few renegade physicians, these pseudoscientists have erected a “front” of respectability which deceives everybody except the trained physician. Many of the most respectable newspapers and magazines as well as broadcasting stations suffer no moral qualms when they accept the remunerative advertising of these near-criminals, and as the mythical ailments grow more numerous and the ballyhoo louder, the gullible public squanders 15 per cent of the total fund it can afford for all medical purposes, in return for which it receives dearly bought spiritual comfort, a mess of worthless compounds and far too often a dose of deadly poison or an equally fatal diagnostic error.

The price of quackery is not limited to the percentage just quoted,—which does not indicate the extent of certain commercial activities not directly related to medical care, but which, in a utopian society, would be under medical jurisdiction. Such are the cosmetic industry, and that part of food merchandising which stresses medical facts in its advertising. Scientific supervision of these matters would undoubtedly divert millions of dollars into more useful channels, possibly in satisfaction of legitimate medical needs.

It would appear from all that has been said herein that a profitable way to improve our system of medical care along social and economic lines would be to devise means by which trained

medical men would be granted legally enforceable supervision over a much greater part of the nation's medical budget than they have at present. It is an axiom of leadership that one who aspires to a position of high command must first show himself capable of a greater degree of self-control than he would expect of obedience from others. Before the medical profession asks the public for the stewardship of the whole program of medical care, it must make certain that it already controls its own special province in a manner consistent with its great moral traditions.

The aspirations of the most noble institutions are confined to the limits of human frailty, there never was or will be a system of medical practice in which every otherwise legitimately qualified practitioner lives up to the ethical standards of the group as a whole. Nonetheless, in order to obtain even a minimum of subservience to ideals, we must pay the price of eternal vigilance over the moral conduct of each professional generation.

Outwardly the American medical profession would appear to have raised its standards to the highest point in history, as shown, for example, by its self-imposed regulations governing medical education and hospitals. These are laudable tendencies, but we must keep in mind that regulations, no matter how strictly enforced, will not of themselves inculcate a feeling of moral responsibility. During this period when the intellectual and technical excellence of the profession is being raised to higher and higher levels, there has occurred simultaneously ever so slight a relaxation in the vigilance exercised over its spiritual standards. At a time when university education has been seized by the trader-artisan class for the purpose of expediting its virtuous acquisition of worldly goods, medicine's ideal of service requires reiteration and splendid, living examples as never before in its history.

The recent medical graduate is usually more conversant with the history and philosophy of capitalism than he is with the cultural background of his own field. If he has to struggle very hard to build up a practice, it is only too probable that he will make use of shopkeepers' ethics before many years have passed, or he may from the very outset have been one of that increasing number of applicants for medical train-

ing who enter medicine for the primary purpose of making money, or who do not distinguish between a medical career and the pursuit of a skilled trade. Walton H. Hamilton, a member of the Committee on the Costs of Medical Care, has written eloquently concerning this subtle influence on medicine of the dollar philosophy so prevalent around us.

The medical profession has, from time out of mind, disclaimed the acquisitive motive. If it is to be true to its high calling, the interests of patients and of physicians alike demand that it be kept out of business.

Here is the heart of the problem of the organization of medicine. A profession has, quite by an historical accident which was not foreseen, fallen into a world of business and is making the adaptation which seems necessary to survival. It has all come about so slowly and so much by stealth that the program of control essential to the maintenance of the integrity of the traditional ideal could not be formulated. As a result the older order of 'private practice' is being transformed into a system of competitive enterprise, which no one has consciously willed and which in insidious ways interferes with the great social task which medicine is to perform.

'The great social task which medicine is to perform'—our generation will do well to bear these words in mind. Medicine has, of course, always performed a remarkable social service—never as a consciously willed result, but only as the incidental outcome of its attention to the individual patient. The "great task" facing us is to make deliberate use of medical science as an instrument of social benefaction. As we find it today, this instrument is an unwieldy affair only partly controlled by physicians, and to a still lesser extent dominated by the traditional medical ideal of service. Who will guide it and by what principles when the future brings an irresistible popular demand that it be used for social purposes? We younger medical men know the proper answer to these questions, let us begin early, first by leading exemplary professional lives, and next by taking a keen interest in the political, social and economic life about us, to prepare ourselves for the intelligent manipulation of a mighty implement which it will one day be our great responsibility to control.

All figures quoted are based on statistics appearing in *Medical Care for the American People* 213 pp. Chicago: The University of Chicago Press, 1932.

vate practice. They in turn used this income almost entirely for personal ends, requiring only a small amount for professional overhead expenses.

Under modern conditions, medical science has become much more comprehensive, and is no longer synonymous with the activities of the handful of men comprising the regular medical profession. Such are the cosmetic industry, and that part of food merchandising which stresses medical facts in its advertising. Scientific supervision of these matters would undoubtedly divert millions of dollars into more useful channels, possibly in satisfaction of legitimate medical needs.

It would appear from all that has been said herein that a profitable way to improve our system of medical care along social and economic lines would be to devise means by which trained

medical men would be granted legally enforceable supervision over a much greater part of the nation's medical budget than they have at present. It is an axiom of leadership that one who aspires to a position of high command must first show himself capable of a greater degree of self-control than he would expect of obedience from others. Before the medical profession asks the public for the stewardship of the whole program of medical care, it must make certain that it already controls its own special province in a manner consistent with its great moral traditions.

The aspirations of the most noble institutions are confined to the limits of human frailty, there never was or will be a system of medical practice in which every otherwise legitimately qualified practitioner lives up to the ethical standards of the group as a whole. Nonetheless, in order to obtain even a minimum of subservience to ideals, we must pay the price of eternal vigilance over the moral conduct of each professional generation.

Outwardly the American medical profession would appear to have raised its standards to the highest point in history, as shown, for example, by its self-imposed regulations governing medical education and hospitals. These are laudable tendencies, but we must keep in mind that regulations, no matter how strictly enforced, will not of themselves inculcate a feeling of moral responsibility. During this period when the intellectual and technical excellence of the profession is being raised to higher and higher levels, there has occurred simultaneously ever so slight a relaxation in the vigilance exercised over its spiritual standards. At a time when university education has been seized by the trader-artisan class for the purpose of expediting its virtuous acquisition of worldly goods, medicine's ideal of service requires reiteration and splendid, living examples as never before in its history.

The recent medical graduate is usually more conversant with the history and philosophy of capitalism than he is with the cultural background of his own field. If he has to struggle very hard to build up a practice, it is only too probable that he will make use of shopkeepers' ethics before many years have passed, or he may from the very outset have been one of that increasing number of applicants for medical train-

ing who enter medicine for the primary purpose of making money, or who do not distinguish between a medical career and the pursuit of a skilled trade. Walton H. Hamilton, a member of the Committee on the Costs of Medical Care, has written eloquently concerning this subtle influence on medicine of the dollar philosophy so prevalent around us.

The medical profession has, from time out of mind, disclaimed the acquisitive motive. If it is to be true to its high calling, the interests of patients and of physicians alike demand that it be kept out of business.

Here is the heart of the problem of the organization of medicine. A profession has, quite by an historical accident which was not foreseen, fallen into a world of business and is making the adaptation which seems necessary to survival. It has all come about so slowly and so much by stealth that the program of control essential to the maintenance of the integrity of the traditional ideal could not be formulated. As a result the older order of private practice is being transformed into a system of competitive enterprise, which no one has consciously willed and which in insidious ways interferes with the great social task which medicine is to perform.

"The great social task which medicine is to perform"—our generation will do well to bear these words in mind. Medicine has, of course, always performed a remarkable social service—never as a consciously willed result, but only as the incidental outcome of its attention to the individual patient. The "great task" facing us is to make deliberate use of medical science as an instrument of social benefaction. As we find it today, this instrument is an unwieldy affair only partly controlled by physicians, and to a still lesser extent dominated by the traditional medical ideal of service. Who will guide it and by what principles when the future brings an irresistible popular demand that it be used for social purposes? We younger medical men know the proper answer to these questions, let us begin early, first by leading exemplary professional lives, and next by taking a keen interest in the political, social and economic life about us, to prepare ourselves for the intelligent manipulation of a mighty implement which it will one day be our great responsibility to control.

ACUTE HEMOLYTIC (LEDERER'S<sup>2</sup>) ANEMIA\*

## REPORT OF A CASE

THOMAS H. MCGAVACK, M.D.†

NEW YORK CITY

THE syndrome of acute hemolytic anemia described by Lederer in 1925<sup>1</sup> has become a distinct clinical entity, characterized by its occurrence in patients under thirty, the absence of any familial blood dyscrasia, a sudden onset, high fever, a rapidly appearing severe macrocytic anemia with reticulocytosis, marked leukocytosis, negative blood cultures, and often complete remission following a single transfusion. The present report deals with a case varying in certain major respects from the above picture, particularly in its complete failure to respond to repeated transfusions.

## CASE REPORT

A J (No D345 37), a 17 year-old girl, was admitted to the hospital on January 16, 1937, complaining of weakness and pain in the left upper quadrant of the abdomen. She stated that she had been well until December 24, 1936, when she developed an upper respiratory infection, associated with fever, mild coryza, sore throat, generalized aching, non-productive cough and weakness. Except for the weakness, these symptoms all disappeared in a few days. On January 5, 1937, there had been a return of the fever, associated with a dull, paracranial headache and followed in 24 hours by deep jaundice and clay-colored stools. On January 11, 1937, the patient became conscious of a large, painful tender mass, rapidly increasing in size, in the left upper quadrant of the abdomen. Associated with it were a septic type of temperature with profuse night sweats and remissions around 4 a. m., increasing pallor, weakness and episodes of epistaxis. The past history included occasional mild attacks of tonsillitis, but was otherwise negative.

Physical examination on admission revealed a very thin, markedly anemic, prostrated, white girl, with a pulse of 120, respirations 24 and temperature 102.6°F. The skin presented a waxy pallor and a lemon yellow tint. The scleras were jaundiced. All mucous membranes were extremely pale, no petechiae were noted. The anterior cervical lymph nodes were slightly enlarged. The heart was enlarged to the left, with the apex impulse visible and palpable 2 cm. to the left of the midclavicular line in the 5th intercostal interspace. The 1st sound was shortened. The rhythm was fetal in type. There was a soft, blowing systolic murmur heard over the entire precordium, with its point of maximum intensity to the left of the sternum in the 3rd intercostal interspace. The blood pressure was 120/70. A tender mass was palpable in the left upper quadrant of the abdomen, extending downward from beneath the subcostal margin to within 1 cm. of the umbilical level, and medially to about 2 cm. from the midline. The liver edge was felt 2 fingerbreadths below the right costal margin. It was soft, smooth and non-tender. There was no ascites.

The blood (Table 1) showed a hemoglobin of 22 per cent, a red cell count of 1,160,000, a color index of 1.0 and a white-cell count of 7600. The differential count revealed 72 per cent polymorphonuclear neutrophils, 16 per cent being immature forms, 1 per cent eosinophils, 23 per cent lymphocytes, 3 per cent monocytes and 1 per cent Rieder cells. There were 140,000 platelets per cubic millimeter. Many microcytes and macrocytes were present in the stained smears. Marked anisocytosis and moderate poikilocytosis and polychromatophilia were noted. In the fragility test hemolysis began at 0.44 and was complete at 0.36. The icteric index was 32.6. A very faint van den Berg reaction of the delayed direct type was found. Urinalysis revealed a dark, amber-colored urine of pH 5.8 and specific gravity 1.015. Albumin, sugar, acetone, diacetic acid and indican were absent; the sediment contained a very few hyaline casts, and a few squamous and cuboidal epithelial cells. None of several blood cultures yielded any growth at the end of 72 hours. The feces were negative for occult blood and for parasites or their ova. Blood Wassermann and Kahn tests were negative with cholesteralized and alcoholic antigens. The sedimentation rate was 35 mm. in 15 minutes, and 42 mm. in 1 hour (cell volume, 15 per cent). Bone marrow blood taken on April 15, showed a differential count as noted in Table 1. Blood typing revealed a Group O response. It is significant that neither agglutination nor hemolysis appeared in cross-matching the patient's serum and the cells of ten donors from this group.

The patient ran a moderate temperature, varying from 99.6 to 104°F rectally throughout the first 63 days of her hospital stay. The spleen remained approximately the same size as on admission until it was removed on February 3 to relieve the symptoms of oozing gums and low platelet count. The spleen measured 20 by 11 by 10 cm. and weighed 900 gm. Five very large infarcts and a number of small ones were present. One of the large infarcts involved the entire depth of the spleen. The pathologist's (Dr. W. E. Youland) report was, in part, as follows:

On microscopic section, the outstanding pathologic features are a primary hypertrophy and hypermitosis of fibroblasts, lymphoid cells, endothelial cells and myeloid cells, including a considerable admixture of eosinophilic myelocytes. There are also small and large mononuclear cells with deeply stained nuclei. Some of these mononuclear cells resembled the transitional cells of the blood; others resembled large plasma cells. A few are mononuclear with abundant eosinophilic granules in their cytoplasm. There are many mitotic figures among these cells.

Dameshek<sup>2</sup> considers these latter cells identical with the type he<sup>3</sup> has previously described as the erythrogon.

Cultures of the spleen, both aerobic and anaerobic, failed to show any growth during a 2 week period of observation. Wherever splenic material had touched blood agar slants and plates, hemolysis rapidly occurred. Such hemolytic activity was demonstrable against the patient's own cells and those of Groups O, A and B. No tests were made with specimens of blood from Group AB. A spec-

\* leukocytes anisocytosis microcytosis macrocytosis and achromia were present in varying degrees in all counts until convalescence was well under way

men of sternal bone marrow showed an active erythroblastic and myeloblastic proliferation.

Among the complications observed during hospitalization were multiple infarctions of the spleen, a pneumonic process in the lung, probably secondary to pulmonary infarction, and cerebral disturbances resulting from the severe anemia. Symptomatic features of the clinical picture were weakness, which was often extreme, dyspnea, traceable at times to pain and at others to the severe anemia, persistent upper abdominal pain, shifting pains in various parts of the body, occasional vomiting, extreme pallor, jaundice and emaciation.

Abdominal pain was one of the most persistent symptoms. Before operation it was referred almost entirely to the left upper quadrant, where a dull, constant soreness and tenderness to palpation existed. Following removal of the spleen, the distress was most marked in the right upper quadrant. Severe exacerbations of sharp, stitching or knife-like pains occurred almost daily. Prior to operation these pains were attributed to multiple splenic infarctions, with constantly increasing tension on the splenic capsule. Vomiting seemed to bear some relation to the episodes of acute exacerbation, the vomitus consisting of simple gastric contents in which free hydrochloric acid was found whenever a test was made. While there was a history of clay-colored stools prior to admission, all bowel movements during hospitalization were of a brownish or greenish brown color, except as influenced by the administration of iron.

After operation, improvement under liver concentrate, ferric ammonium citrate, high liver feeding and ingestion of 15 to 30 gm of bone marrow daily was very slow, and was punctuated both by gastrointestinal upsets and by symptoms referable to the severe anemia. On March 31, 1 week after being first allowed out of bed, the patient developed a very sudden deep jaundice with an icteric index of 125.0. Hemoglobin was found in the urine at this time. Hemosiderin granules were not demonstrated. Blood plasma determinations of hemoglobin were not made. The blood cholesterol was 163 mg per cent and cholesterol esters 105 mg. Clinically this jaundice had practically disappeared by April 3—almost as rapidly as it had occurred. There was, however, still a large amount of bile and urobilinogen in the urine. From April 4 onward the patient ceased to complain of pains in the abdomen, her liver gradually decreased in size, although always remaining palpable, and she continued to improve in strength. Cholecystography on April 9 and again on October 19 revealed a ptosed, hypotonic gall bladder, showing no radiographic evidence of calculi.

Since the patient's discharge on April 16, 1937, her blood count has remained slightly below normal (Table 1). There have been repeated mild episodes of upper abdominal pain, associated with a low grade fever (0.5 to 1°F) and a slightly jaundiced appearance clinically on two occasions, although icteric indices have been within normal limits. Moreover, urine discoloration has been minimal, and not different in day and night specimens. The edge of the liver has receded beneath the costal margin. Subjectively she is asymptomatic.

Tests performed on November 27, 1937, and June 14 and November 12, 1938, were negative for the presence of autoagglutinins and autohemolysis. Observations were made at icebox (5°C), room and incubator (37°C) temperatures. Reactions with human blood cells of Groups O A and B were normal under similar conditions. The Donath-Landsteiner reaction was not done in the first series of tests and was negative in the second and third. On the last mentioned date, a check for the presence of autohemolysis of the type seen in paroxysmal hemo-

globinuria was made, according to the lactic-acid method described by Ham<sup>4</sup> and found positive by Dacie and associates<sup>5</sup> in their more recently reported case.

It is often difficult to classify cases of hemolytic anemia. Dameshek<sup>6</sup> believes that acute hemolytic anemia "may be related to paroxysmal (cold) hemoglobinuria, to paroxysmal nocturnal hemoglobinuria (Marchiafava), to acquired hemolytic icterus, to hemolytic splenomegaly (Banti) and even to congenital hemolytic jaundice." The present patient's course resembles that of acute hemolytic anemia of the Lederer type in the following regards: a family history negative for blood dyscrasias, a sudden onset, the rapid development of a severe anemia without demonstrable cause, evidence of hemolysis as shown by the skin coloration, a positive van den Bergh reaction and hemoglobinuria, demonstrated on one occasion, a macrocytic type of blood response with high reticulocytosis, and the presence of many normoblasts and a few megaloblasts in the circulating blood, and the further indication of very active erythropoiesis as shown by bone-marrow biopsy and study of bone-marrow blood.

Dameshek<sup>6</sup> has been able to demonstrate a hitherto undescribed hemolysin in the serum of patients with acute hemolytic anemia in half to one third of the tests. This is active against cells of the same blood group to which the patient belongs, and against cells of Group O for which, theoretically at least, isohemolysins should not exist. The serum of the case under discussion failed to hemolyze cells from any of ten transfusion donors who belonged to her group (Group O). One would have expected to observe such incompatibility in at least two of the tests made if the case conformed to the type described by Dameshek.

The condition differed from the usual course of Lederer's anemia as follows: the failure of the patient to respond to repeated transfusions, the presence of leukopenia and of thrombocytopenia, the repeated return of episodes of jaundice following splenectomy, and the continuation of mild

anemia and low-grade fever for more than one year following the acute attack. These latter features clinically suggest the type of chronic hemolytic anemia with paroxysmal nocturnal hemoglobinuria described recently by Ham,<sup>4</sup> in which the hemolytic factor is apparently inherent in the red cell and can be activated by altering the hydrogen ion concentration of the blood toward the acid side. Such a "lysin" could not be demonstrated in the present case. Unfortunately Ham does not mention the subsequent course of any of his 3 cases. The patient in the case here reported now seems healthy in every particular save for a very slight anemia and the occasional presence of fever (never exceeding 1.5°F). As originally described by Marchiafava,<sup>7</sup> splenomegaly is not a feature of paroxysmal nocturnal hemoglobinuria. Ham found it in all his cases. Splenomegaly was marked in the present case, and the spleen on microscopic examination showed active reticuloendothelial proliferation with slight erythrophagocytosis.

#### SUMMARY

A case of hemolytic anemia is reported, which in its onset and early behavior simulated that described by Lederer and in its later course suggested Marchiafava's disease, but which has throughout failed to satisfy all the usual criteria for either

## DISEASE OF BESNIER-BOECK-SCHAUMANN

LEON BABALIAN, M.D

PORTLAND, MAINE

IT IS always easy to give a new name to a disease. This can even become an inveterate habit, particularly among dermatologists. It seems, however, that the name of "disease of Besnier-Boeck-Schaumann," recently proposed by Pautrier, of Strasbourg, is well justified to designate a benign and chronic disease, perhaps tuberculous, which reveals itself in cutaneous, ocular, respiratory, lymphatic and osseous manifestations. Of these, the cutaneous ones are the most important, and comprise a considerable part of the sarcoid group.

The purpose of this article is principally to present the point of view of the Strasbourg school concerning a supposedly autonomous affection, without any implication that this conception is entirely original. I am aware that the subject has been given serious treatment in every country. But it is Pautrier who has given the subject its greatest recent stimulus, his point of view remains the most comprehensive of all, and deserves close consideration.

## HISTORY

This new conception was determined by dermatologists, because the cutaneous manifestations of the disease were for a long time the only ones known. According to Pautrier,<sup>8</sup> its genesis was developed in three periods.

In 1889 Besnier described under the name of lupus pernio a kind of chronic chilblain of the face and hands. This disease remained an enigma for a long time. Before Besnier, however, as Hunter<sup>4</sup> says, Hutchinson had already described the "chilblain lupus," but according to Darier<sup>2</sup> this atrophic disease is more nearly related to lupus erythematosus than it is to lupus pernio.

About 1900 Boeck described, first under the name of multiple, benign, dermic sarcoids, then that of miliary lupoids, some lesions which were usually nodular and never ulcerated. This group of sarcoids, today separated, was associated with the tuberculids of Darier.

Lupus pernio and Boeck's sarcoids remained isolated types of lesions until 1916, when Schaumann<sup>12</sup> claimed they were manifestations of the same disease, which he called benign lymphogranulomatosis.

To these three periods we can add a fourth, because since 1935 Pautrier<sup>9-11</sup> has enlarged the noso-

logical picture of Schaumann, and has identified it with an affection of the reticuloendothelial system.

This résumé represents half a century of controversy over the debatable question of tuberculids and the erroneously termed sarcoids.

## PATHOLOGY

*Cutaneous lesions* The disease reveals itself almost always by its cutaneous manifestations, the others being discovered by routine examination. There are two types of cutaneous lesions. The first consists of nodosities the size of a cherry stone, causing small, infiltrated, yellow-red or violaceous elevations, they usually number two or three, but there are sometimes several dozen. These are the so-called large, nodular Boeck's sarcoids. The second type consists of lesions in the form of patches, blue-red, smooth, infiltrated and sometimes a little soft. They may be scattered over the skin in which case they are called Boeck's diffuse, infiltrating sarcoids. A patch is often located on the nose, and is then called lupus pernio. Sometimes one is located on a finger, possibly resulting in a fusiform deformation resembling that caused by spina ventosa.

No matter of what size, these lesions under glass pressure present translucent, miliary grains resembling those of lupus vulgaris, hence the term miliary lupoids, also given them. They persist for several months or years without ulceration, sometimes they are reabsorbed spontaneously. They are never painful, nor do they itch.

*Ocular lesions* These are next in frequency to the cutaneous lesions. They consist of obstinate conjunctivitis, and sometimes of tenacious iritis. Recently Pautrier<sup>11, 13</sup> connected with the disease of Besnier-Boeck-Schaumann an affection known to ophthalmologists as the syndrome of Heerfordt (of Copenhagen), which had until then remained an enigma. This syndrome consists of iridochoroiditis associated with bilateral parotitis, peripheral facial paralysis, recurrent paralysis and often cutaneous manifestations. Lastly, some cases of granular conjunctivitis of Parinaud are undoubtedly associated with the disease of Besnier-Boeck-Schaumann.<sup>5</sup>

*Lymphatic lesions* These always evolve unnoticed, and must be searched out systematically.

The tonsils may be enlarged, but their lesions are shown only by histological examination. In the groin, axilla, neck and epitrochlear regions the nodes may become enlarged to the size of a hazel nut. They remain painless and do not adhere to the subjacent tissues. One lymphatic ganglion is always attacked, namely the tracheobronchial group. One must not expect to find in such a case the picture of massive tracheobronchial adenopathy, its existence is revealed only by routine x-ray examination. In some cases, however, the ganglionic reaction is serious, the lesion invading the mediastinum and giving the appearance of Hodgkin's disease.

*Respiratory lesions* The attack on the lungs may be pronounced, it evolves without symptoms and without changes demonstrable by percussion and auscultation. One finds by x-ray examination a multitude of miliary spots, scattered in both lungs, principally in the upper two thirds. These granulations are dense and have fuzzy contours, they may become confluent and be connected by a network of tissue of increased density. They may be so numerous as to give a diffused opacity when examined by radioscopy. One must again point out that these lesions develop without fever and unnoticed. They are, says Pautrier,<sup>10</sup> a radiological surprise, exactly like those of the "cold, diffuse, miliary tuberculosis" recently described by Swiss authors, moreover, they offer some astonishing analogies with them.

The mucous membrane of the nose may be invaded by small granulations, white or pink, slightly soft and the size of a pinhead.

*Osseous lesions* Often one finds curious alterations of the bones, principally those of the fingers. The lesions develop unnoticed and are radiological discoveries. They consist in areas of rarefaction, which lead to the formation of well-circumscribed cystic cavities. They may persist for several years. Schaumann<sup>12</sup> considers them a major sign of his lymphogranulomatosis.

*Other visceral lesions* The lesions of this disease may occur in the spleen, liver or kidneys, but never produce symptoms. They can be recognized only by histological examination in case of death from some other cause, this affection never being fatal.

*Alterations of the blood* Though Schaumann attaches extreme importance to changes in the blood, they are infrequent and merely consist of an increase in monocytes.

*Miscellaneous lesions* The picture of the disease of Besnier-Boeck-Schaumann is not limited, however, by the above lesions. One hears of certain cases of diabetes insipidus which may be caused by this affection.<sup>6</sup> One may expect to find

a broadening of its field in other cutaneous manifestations, as, for instance, unexplained and atypical erythrodermic or keratodermic patches. It would not surprise me to find, before long, associated with this disease certain forms of acne or sclerodactylia (which I have seen coexisting with lupus pernio) or of lichen—particularly lichen nitidus, so rich in epithelioid cells, which, as we shall see, are a distinguishing characteristic of the disease of Besnier-Boeck-Schaumann.

#### DIAGNOSIS

This affection is frequent in northern countries. It is usually hopelessly chronic, undergoing recrudescence in winter. Sometimes patients improve spontaneously. The condition is compatible with a fair state of general health.

The diagnosis is not always simple. One must remember it when confronted by papulous or nodular, acneiform and chronic cutaneous lesions, by chronic chilblains, by unimproved adenopathy or by tenacious ocular lesions. In certain cases the research must be extended in order to eliminate true tuberculides, true but persistent chilblains, spina ventosa, "cold, diffuse miliary tuberculosis" or even Hodgkin's disease.

X-ray examination is essential to diagnosis, and a blood count is occasionally found useful. Schaumann<sup>1</sup> attaches decided importance to the cutaneous reaction to tuberculin, which must here be negative. But there is no rule without an exception, especially in this reaction. Moreover, guinea pigs inoculated with fragments of all forms of tissue or with blood never develop tuberculosis, a fact of the utmost scientific interest.

#### HISTOLOGY

It is the histological examination that definitely determines the diagnosis of this disease. No matter where the condition manifests itself, whether in the skin, lymph nodes, tonsils, parotid glands, lungs or bones, it invariably produces an identical type of lesion: infiltration consisting of nodules of epithelioid cells. The nodules are surrounded by scattered lymphocytes, but there are never dense zones of lymphocytic infiltration. Giant cells are exceptional. Foci of necrosis are never found. Around the nodules no reaction of the collagenous tissue exists: the masses of epithelioid cells are set in the surrounding tissue like foreign bodies which are well tolerated. Thus the lesions lack a true tuberculous structure, although they might be considered as imperfectly developed tuberculous follicles with a very light peripheral inflammatory reaction. In some cases, however, the presence of numerous giant cells seems to indicate the existence of a transitory form between the disease of

Besnier-Boeck-Schaumann and tuberculosis<sup>7</sup> On the other hand, in very rare cases there are wandering cells of different types, which may prove the possibility of an evolution toward granulomatosis

#### ETIOLOGY

Should we consider the disease of Besnier-Boeck-Schaumann a tuberculide, that is an attenuated form of tuberculosis, due either to a degenerated bacillus, a tuberculous toxin or a filterable virus? Or should we, with Schaumann, invoke an inactive tuberculosis of bovine origin? Both these hypotheses, according to Danish authors,<sup>1</sup> appear improbable because of the frequent negativity of the tuberculin reaction and the constant negativity of the inoculation of guinea pigs. These authors and Pautrier<sup>3</sup> believe the condition to be an autonomous infectious granulomatosis, due to a new virus which may be placed between those of tuberculosis and leprosy.

As for the cases complicated by tuberculosis, this does not prove, as some authors contend, the tuberculous nature of this disease, as Pautrier<sup>13</sup> says, tuberculosis develops in such cases on a ground already weakened by another infection. Moreover, it is well known that the disease occurs frequently in northern countries where tuberculosis is especially rare.

May not the disease of Besnier-Boeck-Schaumann be a syndrome determined by several causes, as Darier<sup>2</sup> admitted in the case of all cutaneous sarcoids? As to this, let us recall that the epithelioid-cell reaction is not a specific response to the presence of the tubercle bacillus, but may be produced by materials derived from other organisms (Jordon and Osborne<sup>3</sup>).

#### TREATMENT

It is difficult to formulate a treatment for a disease the cause of which is uncertain, and which presents spontaneous improvement. The usual treatment is the same as that for tuberculides, that is, organic arsenic and intradermal injections

of tuberculin, this treatment was the only effective one in two cases reported by Lesné<sup>13</sup>. Lomholt,<sup>1</sup> true to the Danish etiologic conception, prefers preparations derived from chaulmoogra.

#### SUMMARY

The disease of Besnier-Boeck-Schaumann, extremely variable in its clinical forms and in its evolutionary methods, usually manifests itself by persistent but not pronounced manifestations, reaching the eyes, the respiratory apparatus, the skeleton, the lymphoid organs several glands such as the parotids, and the spleen, liver and kidneys. But the skin is above all its favorite site, there it reveals itself by several lesions which belong to the group of sarcoids. No matter where the disease shows itself, the lesion is invariably identical, with epithelioid cells. By some of its aspects it allies itself with attenuated tuberculosis, but its nature is not yet absolutely determined. It may be an autonomous affection, or perhaps merely a syndrome caused by one of several factors.

## PAPERS FROM THE FAULKNER HOSPITAL

## POPLITEAL ANEURYSM

## Report of Two Cases

ARTHUR R. KIMPTON, M.D.,\* AND ERIC R. SANDERSON, M.D.†

BOSTON

THE popliteal artery, with the exception of the aorta, is the most frequent site of the formation of an aneurysm. This fact is not generally recognized, nor is the fact that popliteal aneurysms are by far the most frequent of the operable types. Matas<sup>1</sup> reported a series of 106 operable aneurysms covering all the important regions of the body, it was found that 62 (58 per cent) involved the popliteal artery. In the same series, 63 (66 per cent) of 95 aneurysms involving the arteries of the lower extremities, including the iliac vessels, were popliteal. Matas quoted Delbet as finding that aneurysms of the popliteal artery constitute over one third of all the peripheral and surgical aneurysms.

Popliteal aneurysms differ from those involving other arteries in that they generally tend to progress more rapidly and that the incidence of severe and unheralded complications is high. Spontaneous gangrene frequently occurs following thrombosis. Furthermore, as the aneurysm expands there is gradual stretching and absorption of the surrounding ligaments, the pulsating tumor may erode the adjacent bone, in time there may be rupture into the soft tissues or the knee joint. The latter complication is a constant and serious menace in any case of the disease.<sup>2</sup>

The anatomical location of the popliteal artery favors the development of complications, since the vessel courses through a small, tightly bound space replete with important structures.

Matas classifies aneurysms of the popliteal artery in three categories, according to their anatomical location: upper, middle and lower. The upper, or femoropopliteal ones, have room for expansion and, what is more important, involve a relatively small number of collaterals. Those of the lower or popliteocrural group are forced to develop in a small space, which also includes the popliteal vein and the peroneal and popliteal nerves. The danger of gangrene is more imminent in the latter group, since it is easy for a plug of thrombus to lodge at the popliteal bifurcation or in one of the main collaterals in that region. If this occurs, the only avenue for the collateral circulation of the leg is through the smaller arteries arising from the popliteal artery in the region of the knee joint. Likewise, pressure on the

vein may result in gangrene, and involvement of the nerves may cause trophic disturbances.

There are several important etiologic factors in the production of popliteal aneurysms, probably the most important of which is trauma, although they are rarely of purely traumatic origin. In the majority of cases the patient cannot recall any single outstanding trauma to the popliteal region. Delbet, again quoted by Matas,<sup>1</sup> believes that the internal and middle tunics of the artery are ruptured during violent lifting efforts in which the intra-arterial pressure is elevated. This rupture may be so insignificant as to cause no appreciable symptoms at the outset, or may be severe enough to cause immediate thrombosis in the vessel, with subsequent symptoms of arterial gangrene. Arteriovenous and false aneurysms may also result from trauma. Arteriosclerosis is a predisposing factor in the production of the aneurysmal sac. Syphilis usually causes aneurysms in the larger arteries of the body, but occasionally one finds that a popliteal aneurysm is syphilitic in origin. A rare cause is lodgment of septic emboli on the intima, mycotic aneurysms develop in this manner. Wells and his associates<sup>3</sup> have failed to find a case of congenital aneurysm of the popliteal artery, and they also doubt whether a dissecting aneurysm could occur there, since the coats of the arterial wall are thin and indistinct.

Diagnosis is easy in the advanced case, which presents the typical picture of a pulsating tumor transmitting a loud bruit and thrill. The same clinical signs, however, may be found in vascular tumors, and arteriography is employed to differentiate the two conditions. This is also used to determine the character and location of the disease process and the presence and adequacy of collateral circulation. The use of Thorotrast has been virtually abandoned, since it has been shown that particles of radio-active thorium dioxide are stored in the reticuloendothelial system of the spleen and liver after intravenous administration. Because of this property the drug has not been accepted by the Council on Pharmacy and Chemistry<sup>3</sup> of the American Medical Association. In 1937, an editorial<sup>4</sup> in the *Journal of the American Medical Association* re-emphasized the hazard. While as many as ten or fifteen years may elapse between the administration of Thorotrast and the resultant tissue changes, the length of this period

\*Member of associate staff, Faulkner Hospital, Boston.  
†Faulkner Hospital, Boston.

is no indication of ultimate safety. The editorial goes on to say "Recent reports emphasize the proclivity of this substance to produce necrosis and malignant change in tissues with which it remains in contact." Diodrast and similar iodine preparations used for excretory urography are excreted rapidly, and are relatively non-toxic in the doses used. They have an advantage over sodium iodide in that they cause no damage to the intima of the vessels and no pain on intravascular injection. The density of the shadow cast is entirely satisfactory, although not so clear cut as that of Thorotrast.<sup>6</sup>

Yater's<sup>8</sup> technic of administration follows. While an assistant compresses the femoral artery as it emerges under the inguinal ligament, 20 or 25 cc of Thorotrast is injected into the artery in Scarpa's triangle. An x-ray is taken immediately, five or six pulsations are then permitted to pass along the vessel, and another x-ray is taken. In the two cases reported below, Diodrast was injected directly into the aneurysm, a tourniquet being applied on the thigh and lower leg in order to prevent too rapid escape of the contrast medium. The x-ray films obtained in this manner are entirely satisfactory, and the procedure is easily carried out.

Theis<sup>7</sup> stresses early diagnosis, stating "Aneurysms of the popliteal artery produce disturbances in the peripheral circulation even before the onset of local symptoms in the popliteal space. With the arterial pressure at least partially expended in dilating the aneurysmal sac, a corresponding reduction in pressure occurs in the distal circulation. Accordingly, the peripheral arterial pulsations and temperature readings are reduced." He recommends that all cases of peripheral circulatory disturbance be studied by temperature readings and by oscillomograph and differential tests for organic and spastic vascular diseases.

The treatment of popliteal aneurysms consists of promoting collateral circulation and evaluating its efficiency, then surgical exploration, adapting the type of procedure followed to the type of aneurysm found, and finally further development of the collateral circulation postoperatively.

The measures most commonly used to promote collateral circulation are temporary occlusion of the artery above the aneurysm, sympathectomy and passive vascular exercise. Matas<sup>8</sup> stresses the following methods of testing the efficiency of the circulation: (1) the hyperemic reaction or modified Moszkowicz color test, (2) oscillometric manometry to determine peripheral blood pressure after temporary occlusion of the main artery, and (3) the clinical demonstration of a persistent cir-

ulation and nutrition of the peripheral parts in spite of permanent absence of the peripheral pulses.

Of the surgical procedures employed, those of Matas<sup>1</sup> are most generally applicable. He describes three types of operation. The first is obliterative endoaneurysmorrhaphy (the fundamental procedure), consisting of opening the sac and closing all visible orifices in it with fine chromic catgut or silk sutures, following which the sac is obliterated in one of several ways. Thus the artery is completely occluded. The procedure is applicable particularly to fusiform aneurysms in which the aneurysmal sac consists of a dilatation of the artery. The method is also used in cases in which the aneurysmal wall is friable and does not lend itself to reconstructive procedures.

Restorative aneurysmorrhaphy is used in sacular aneurysms where the greater portion of the arterial wall is normal, and the aneurysm forms a pouch protruding from it. The sac is opened and the single orifice is closed with a continued suture, thus preventing the flow of blood into the sac but leaving the lumen of the main artery patent. Obliteration of the sac is carried out by approximation of the endothelial surfaces.

Reconstructive aneurysmorrhaphy is applicable to fusiform aneurysms in which the sac walls are favorable to reconstructive surgery. The two openings must lie on the same level, in close proximity. The continuity of the artery is restored by forming a new arterial wall from the sac, suturing the wall about a guide previously introduced into the artery. Since one is dealing with a diseased vessel wall there is a marked tendency toward recurrence. It is rarely possible to perform this operation successfully, and further surgery is usually required.

Unless the picture presented is one of ruptured aneurysm, one should await development of adequate collateral circulation before operation is undertaken.

#### CASE REPORTS

*Case 1* F. B., a 27-year-old store manager, entered the Faulkner Hospital complaining of a swelling in the back of the right knee which had been present for 6 weeks. Previously he had been in good health. The swelling caused him no great inconvenience until 2 weeks before entry, when it suddenly started to increase in size. After this, pain began and gradually progressed to a severe, steady ache which required medication for relief at the time of admission. There was no history of recent injury.

The past history was noncontributory except for scarlet fever during childhood and an injury to the right knee by a fall 9 years before entry. At that time the patient sustained a laceration requiring four sutures. His past history was otherwise essentially negative, and the family history was irrelevant.

Physical examination revealed a well-developed, well-nourished man. The temperature was 100°F and the

blood pressure 140/70. The heart sounds were regular and of good quality, and there were no murmurs. The abdomen and genitalia were negative. There was an old scar on the anterior surface of the right knee. In the right popliteal region there was a diffuse, markedly tender swelling about the size of an orange. This was pulsating and a thrill was felt. On auscultation a distinct bruit was heard.

The urine was normal. The white-cell count was 10,200 and the differential count was normal. The red cells were normal, as were the hemoglobin and platelets. A blood Hinton test was negative.

X-ray films of the right knee showed no bone or joint changes. There was a soft tissue tumor in the popliteal area about 5 cm. in diameter, consistent with a diagnosis of popliteal aneurysm. On the day following entry, films were taken after injection of the tumor mass with Diodrast solution (Fig 1). There was partial filling of a cavity

Figure 1 Case 1

*Ruptured aneurysm of the popliteal artery demonstrated by the injection of Diodrast directly into the sac*

measuring 9 cm. in diameter. The posterior wall showed a rather laminated structure. There was a small amount of extravasation posteriorly into the subcutaneous tissue and partial filling of a cylindrical structure 4 cm. long which was apparently the popliteal artery. The diagnosis was large popliteal aneurysm on the right, containing a large clot partially organized.

During the first 3 days in the hospital the patient had terrific pain, with a rapid increase of swelling of the right knee and lower leg. The temperature rose daily to 101°F, the pulse rate varied between 94 and 120, and the respirations were 20. Because of the intense pain and increase in swelling, operation was performed 3 days after admission, without further study.

Under spinal anesthesia, an incision 20 cm. long was made over the popliteal space. Dissection was carried down to the popliteal vessels, and a large ruptured aneurysm was found. Clot and connective tissue filled the whole popliteal space, and there was considerable edema. Proximal and distal openings into the sac were found and sutured in two layers, following which the entire sac was imbricated. On removal of the tourniquet there was a little bleeding and pulsation of the small vessels below the sac, indicative of some collateral circulation.

Postoperatively the leg was kept in the prone position with a heated cradle over it. During the first few days

two small decubitus ulcers appeared over the external malleolus and the patient had anesthesia of the sole and toes and lateral aspect of the leg to the mid-calf. During the first 6 postoperative days the temperature ranged from 98.6 to 102°F, and the pulse from 90 to 120. Collateral circulation improved gradually so that by the 7th postoperative day there seemed little question that the circulation would be adequate. The skin anesthesia remained as described, but the patient became able to move his toes and foot. On the 10th postoperative day Buerger's exercises with slight massage were started. The following day the upper and lower poles of the incision began to discharge large amounts of thick, foul pus from which *Streptococcus hemolyticus* was cultured.\* Hot flaxseed poultices were applied and exercises and massage were continued. The patient was allowed up in a wheel-chair on the 16th postoperative day, but there was still some purulent drainage from the wound. The skin anesthesia was considerably less than before and there was good movement of the toes and foot. Four days later, when the patient was on crutches for the first time, the leg became extremely cyanotic, but this disappeared completely when he returned to bed. Vasculator treatment was begun for 20 minutes twice daily on the 21st postoperative day and was continued for 4 days, at the end of which time he was discharged.

Seventeen months after operation the patient still walked with a slight limp and there was considerable atrophy of the leg. It was, however, a well functioning limb.

**Case 2** J. McC., a 34-year-old dentist, entered the Faulkner Hospital complaining of a swelling in the back of the left knee. The swelling was first noticed about 2 weeks prior to entry, and there was no known trauma preceding its appearance. During the 2 days before admission it had become painful, but otherwise it had not inconvenienced the patient in any way. The past history was noncontributory except for the usual childhood diseases and scarlet fever. There was a knee injury sustained in playing football 19 years before entry, but the patient did not remember whether this involved the left or the right knee. The rest of the past history and the family history were irrelevant.

Physical examination revealed a well-developed man in excellent general condition. The heart, lungs and abdomen were normal. The left leg was considerably larger than the right. The superficial veins were moderately distended, and in the left popliteal space there was a round, smooth, slightly tender mass, which pulsated visibly. A definite bruit was audible. There was no clinical evidence of syphilis, and blood Wassermann and Hinton tests were negative.

Urinalysis revealed no abnormalities. The white-cell count was 13,450, and the differential count was normal. The red-cell count and hemoglobin were normal.

On the day of admission a flat film of the knee showed no bone or joint changes and no soft tissue masses. Injection of Diodrast directly into the mass demonstrated a sac measuring 5.5 cm. in diameter and communicating with the arterial system (Fig 2). There was a small amount of Diodrast in the lower portion of the femoral artery, and the sac was located in the popliteal space. The large branches of the popliteal artery were well outlined. Following the injection of the Diodrast there was no visible pulsation, tactile pulsation or bruit, a collateral vessel gave a flush to the mid-calf. This seemed best ex-

\*These cultures, the short duration of the lesion and the fever all suggest the possibility of a mycotic aneurysm but there is no definite proof that infection was the primary etiologic factor.

plained by clotting in the sac following the insertion of the needle.

Operation was performed on the 9th day. A tourniquet was adjusted on the thigh, and a longitudinal incision was made over the popliteal space. The popliteal artery was exposed above and below the aneurysm. On being opened the sac was found to contain recent but fairly well-organized clot. The aneurysm was saccular in type and there were three openings into it. These were su-

Postoperatively the leg was kept in a prone position. The color of the extremity remained good, leg and foot motions were normal, and there were no areas of anesthesia or paresthesia. Bicycle exercises were begun, with no untoward effect. The patient got out of bed on the 12th postoperative day and was discharged home 4 days later.

Twenty-two months after operation the patient was entirely free from symptoms referable to the aneurysm or to the operation.

#### SUMMARY

Of the peripheral arteries, the popliteal is the commonest site of aneurysm formation.

Owing to the anatomic relations of the popliteal artery, complications are of frequent occurrence in aneurysms arising from this vessel. The frequency and severity of these complications vary with the segment of the artery involved.

Trauma and arteriosclerosis are the most important predisposing factors to the development of popliteal aneurysms.

The use of Thorotrast in arteriography may be dangerous and should be abandoned in favor of Diodrast.

The treatment of popliteal aneurysms is discussed, and two cases are reported.

tured with mattress sutures of chromic catgut in two rows and the entire sac was imbricated in three layers. There was arterial bleeding of the minor vessels in the fascia and fat, and a definite hyperemia below the site of the aneurysm.

## CASE RECORDS OF THE FAULKNER HOSPITAL

Antemortem and Postmortem Records as Used in Monthly  
Clinicopathological Conferences*Directed by J BEACH HAZARD, MD*

## CASE 6382

## PRESENTATION OF CASE

*First Admission* A seventy-two-year-old, American business man was admitted with the complaints of fatigue and general weakness.

About nine months preceding admission, he noticed that he became short of breath readily. Soon after this he developed a sore throat, which was associated with a fever and with a cough. After four weeks these symptoms disappeared, and the patient was fairly well except for a feeling of fatigue. One month before entry, marked dyspnea developed and was accompanied by palpitation. He also noticed that he was becoming pale. During a period of two weeks at this time his hemoglobin was said to have dropped from 77 to 35 per cent. In two months there had been a weight loss of about 15 pounds. A blood examination done about a week before admission showed a red-cell count of 1,300,000 with a hemoglobin of 25 per cent (Sahli), and a white cell count of 1300 with 24 per cent polymorphonuclears, 64 per cent lymphocytes, 8 per cent monocytes, 1 per cent eosinophils and 1 per cent basophils. The mean corpuscular volume was 99 cu  $\mu$ . The red cells showed macrocytosis and no achromia, platelets were rare in smears. A platelet count was 23,000, 25 per cent reticulocytes were present. Treatment preceding entry consisted of intramuscular liver extract, Ferrosate, hydrochloric acid and a diet which included liver, oysters, tripe and clams. In spite of therapeutic procedures, however, the patient's course was steadily downhill.

A past history revealed that the patient had had incipient tuberculosis forty years before admission. He had had measles, mumps, pertussis and scarlet fever. Two years preceding entry he had been in an automobile accident, with a resulting hematoma of the right leg. The family history was irrelevant.

Physical examination revealed a well-developed and well-nourished, very pale man lying comfortably in bed. No icterus was present. The pupils reacted to light and accommodation. No hemorrhages were present in the retinas. All teeth were absent. The throat was negative. No lymph nodes were palpable. The heart sounds were of good quality, with no murmurs, and the rate regular and rapid. The lungs were clear throughout. Examination of the abdomen showed no enlargement of the spleen. One observer noted

that the liver edge was two fingerbreadths below the right costal margin and presented a questionable irregularity of the edge. Bilateral inguinal hernias were present. The genitalia were negative. Rectal examination revealed a prostate of average consistence but with slight enlargement of the right lateral lobe. The knee jerks were equal but active. The temperature on admission was 99°F, the pulse rate 112, and the respirations 24. The blood pressure was 140 systolic, 58 diastolic.

Urinalysis showed a clear straw-colored specimen with acid reaction and a specific gravity of 1.015 and with no albumin, sugar, bile, diacetic acid or acetone. The sediment showed 1 to 3 white blood cells per high-power field but was otherwise not remarkable. A urobilinogen test was positive through a dilution of 1:8. The white-cell count was 2000, and the red-cell count 1,300,000 with a hemoglobin of 35 per cent (Sahli). A differential count showed 41 per cent polymorphonuclears, 1 per cent monocytes, 55 per cent large lymphocytes and 3 per cent small lymphocytes. There were frequent macrocytes, moderate anisocytosis, slight poikilocytosis and no achromia. Platelets appeared markedly reduced. A rare nucleated red cell was seen. The bleeding time was 6 minutes, and the coagulation time 15 minutes (Lee and White) with no retraction of the clot in twenty-four hours. A blood Hinton test was doubtful. A stool examination was negative.

X-ray films of the dorsal and lumbar regions of the spine, pelvis and upper femurs showed no definite destructive changes. The texture throughout the symphysis, including the rami, was definitely coarse as compared to the normal. The lumbar vertebrae appeared normal. The upper dorsal vertebrae were rather granular but showed no definite areas of destruction. X-ray films of the chest showed a striated density extending from the hilum to both apices. The lung markings were prominent throughout the remainder of both lung fields. The hilar areas were increased in density. There was slight retraction of the apical pleura on the right.

During two weeks' stay in the hospital the patient was placed on an anemia diet and was given four transfusions of 500 to 650 cc of whole blood each. A bone-marrow biopsy was performed four days following admission. Successive red-cell counts

were 1,600,000 with a hemoglobin of 41 per cent, 1,900,000 with a hemoglobin of 57 per cent and, on the date of discharge, 3,200,000 with a hemoglobin of 66 per cent. A white-cell count two days after admission was 1050 with 42 per cent polymorphonuclears and 58 per cent lymphocytes. Smears showed moderate anisocytosis, slight polychromasia and apparently decreased platelets. The white-cell count five days before discharge was 2000. The temperature varied irregularly up to 102°F throughout his stay.

*Second Admission* (three months later). Following discharge the patient showed steady improvement. Treatment consisted of a high-vitamin diet and, at first, intramuscular liver extract, then liver by mouth. About four weeks preceding his second admission he noted a swelling of the right testicle, which appeared suddenly and then increased gradually in size.

Physical examination showed a well-developed and well-nourished man with good color. Except for an enlarged scrotum and bilateral inguinal hernias, examination was essentially negative. Local examination of the scrotum showed a slightly tender mass on the right that seemed to involve the whole testicle. The temperature was 97.4°F, the pulse rate 110, the respirations 20 and the blood pressure 150 systolic, 88 diastolic. The white-cell count was 6800, and the red-cell count 4,100,000 with a hemoglobin of 88 per cent. A differential count showed 60 per cent polymorphonuclears, 36 per cent lymphocytes and 4 per cent monocytes. The red blood cells and platelets appeared normal. A urinalysis showed no albumin or sugar. A blood Hinton test was negative.

Two days after admission an orchidectomy was performed. The postoperative course was uneventful.

#### DIFFERENTIAL DIAGNOSIS

DR MAURICE B. STRAUSS. This patient had a profound disturbance involving all the formed elements of the bone marrow,—erythrocytes, leukocytes and platelets,—in other words a pancytopenia. Such a condition cannot result from either blood loss or increased blood destruction. The severity of the leukopenia is against pernicious anemia, although I have rarely seen cases with the granulocytes and platelets as low as this. However, since the patient apparently received an adequate amount of liver extract intramuscularly and failed to respond, pernicious anemia may be excluded, although in favor of such a diagnosis is the remission lasting for at least three months while the patient received further liver therapy.

If we may exclude pernicious anemia, what then

may give this type of blood picture? There is no history of exposure to benzol, arsphenamine, gold salts or other drugs, of external irradiation from x-rays or radium or of the ingestion of radioactive substances. There is nothing to suggest chronic nitrogen retention, and further, nucleated red blood cells are not found in anemia from this cause. Chronic infections may produce this picture. However, there is insufficient evidence here for a chronic infection of sufficient severity to do this. Fever up to 102°F is not unusual with severe anemia.

We are therefore left with two main causes of myelophthisis infiltrative (idiopathic) aplasia and pseudo-aplasia of the bone marrow. We can exclude metastatic carcinoma, hypernephroma, myeloma, plasmoma, aleukemic myelosis, Hodgkin's disease, tuberculosis of the bone marrow and osteosclerosis because spontaneous remission of anemia does not occur in these conditions. However, the nucleated red blood cells are strongly suggestive of such an infiltrative lesion. These cells also are evidence against an aleukemic lymphatic leukemia.

Aplasia and pseudo-aplasia of the marrow can give exactly this blood picture except for the nucleated red blood cells. Remissions, although rare, do occur. Diagnosis, however, can only be made positively by bone-marrow biopsy, remembering that at least half the cases of so-called aplastic anemia show a hyperplastic marrow.

The changes in the bones evidenced by x-ray examination suggest Paget's disease. The prostate should not show carcinoma. The tender testicular swelling is probably inflammatory, possibly tuberculous, although tuberculosis is almost always limited at first to the epididymis.

In conclusion, then, the picture presented here is most consistent with a spontaneous remission of a primary bone-marrow disturbance either of an infiltrative aplastic or of a pseudo-aplastic type.

#### CLINICAL DIAGNOSES

Aplastic anemia  
Bilateral apical tuberculosis, fibroid type  
Tuberculous epididymitis

#### DR. STRAUSS'S DIAGNOSES

Anemia of infiltrative aplastic or pseudo-aplastic type  
Tuberculous epididymitis (?)

#### ANATOMICAL DIAGNOSES

(Pancytopenia)  
Miliary tuberculosis of bone marrow  
Tuberculous epididymitis  
Hydrocele

## PATHOLOGICAL DISCUSSION

DR J BEACH HAZARD Dr Strauss has summarized the case well. The bone-marrow biopsy was interesting in two respects. In spite of the severe anemia the marrow showed an increased cellularity with moderate hyperplasia of the red-cell series. That is not the classical picture one associates with aplastic anemia, of course, but it is well recognized that a fair percentage of such cases will show a cellular marrow. An additional finding was the presence of tubercles, but to date no acid-fast bacilli have been demonstrated in them. The specimen from the operation was composed in part of a hydrocele which, when opened, revealed an enlarged epididymis. The latter presented numerous yellow, often semi-fluid areas, in smears of which many acid-fast bacilli were found. Histologically there was a typical tuberculous epididymitis.

The appearance of the marrow lesions and the finding subsequently of tuberculosis elsewhere has led us to make a diagnosis of miliary tuberculosis of the bone marrow. The blood picture was generally consistent with aplastic anemia. Unfortunately the bone-marrow biopsy did not show the acellularity of typical aplastic anemia, but as stated, a certain number of cases may show hyperplasia. The question of the relation between the tubercles and the anemia arises. Cases of miliary tuberculosis do develop severe anemia, but to my knowledge, remissions do not occur. One is still tempted, however, to believe a relation exists in this case, and perhaps the future course of the patient may prove it.

DR EDWARD L. YOUNG, JR. Was the testicle involved?

DR HAZARD No.

DR STRAUSS Miliary tuberculosis of the bone marrow is a relatively rare condition which is generally associated with disseminated miliary tuberculosis and is usually fatal.

Most of the cases of clinical, aplastic anemia which we have seen have shown normoplastic or hyperplastic marrows. The term pseudo-aplastic anemia may be a better term for an anemia with a blood picture suggesting aplasia but with a marrow that is normoplastic or hyperplastic.

DR JAMES A. HALSTED Are there not some cases of acute aplastic anemia that recover spontaneously? I believe Dr Diamond has had four or five at the Children's Hospital following measles and mild upper-respiratory infections.

DR STRAUSS We have seen a few patients with pseudo-aplastic anemia who had remissions for limited periods of time, seldom however with a complete return of the blood to a normal state.

\* \* \*

Subsequent to this discussion, the patient developed a severe anemia and died, in spite of frequent transfusions. No autopsy was obtained.

## CASE 6386

## PRESENTATION OF CASE

A forty-year-old, Irish-American housewife entered the hospital with the complaint of pain in the right flank.

Nine years previous to admission she had had an attack of pain in both flanks associated with some difficulty in urination and was admitted to a hospital for treatment. At this time a diagnosis of pyelitis was made. About one year later she had had an attack of pain in the right lower quadrant which was diagnosed appendicitis, and an appendectomy performed. The appendix appeared normal, the peritoneal cavity was explored further, but no abnormalities were revealed. Cystoscopic and pyelographic examinations were made eleven days following the operation and showed some irregularity of the kidney pelves and what appeared to be calcified masses. A diagnosis of pyelitis was made, and the patient discharged. During the succeeding years intermittent attacks of dysuria occurred and were associated with chills and fever, and with pain and tenderness in the flanks. For several months preceding admission she had been free of symptoms, but two days before entry she experienced severe pain in the right upper quadrant, associated with nausea, vomiting and some fever. There was no dysuria. The pain became progressively worse and extended around to the right flank. She saw her physician and was referred to the hospital for observation.

Her past history revealed that she had had measles, mumps and whooping cough. When three years old a drainage of the right hip was performed, apparently for osteomyelitis. At the age of twenty-one she had had an operation in the right lower quadrant for intestinal obstruction, the cause of which was not known. Fourteen years before entry, following a stillbirth, there was swelling of the right hip, and a second incision and drainage. Catamenia had not been abnormal.

The patient's father and mother died of unknown cause while she was a child. There was no history of familial disease. She had been married for fifteen years, and except for the stillbirth, no pregnancies had occurred.

Physical examination showed a well-developed and well-nourished woman in apparent agony. The temperature was 100°F, the pulse 100, the

respirations 22, and the blood pressure 88 systolic, 64 diastolic. The skin was warm, and there was no general lymph-node enlargement. Examination of the eyes, teeth, throat, heart and lungs was negative. The diaphragm was apparently higher than usual on the right. Abdominal examination showed spasm and a questionable mass in the right upper quadrant, and tenderness which extended around the right flank. A markedly tender spot was present in the right costovertebral angle. There was no tenderness in the left upper quadrant, in either lower quadrant, in the left costovertebral angle or over the spine. There was a definite shortening of the right leg. An old scar was present over the head of the right femur. There was some limitation of motion on flexion of the right hip, but no definite ankylosis. Knee jerks were present. Rectal and pelvic examinations were negative.

A catheterized specimen of urine with a cloudy straw color showed an acid reaction, a specific gravity of 1.011, a trace of albumin and no sugar, and the sediment contained 10 to 20 erythrocytes, 20 to 30 leukocytes and 3 to 10 squamous cells per high-power field. The white-blood-cell count was 29,000, and the red-cell count 4,700,000 with a hemoglobin of 80 per cent (Sahli). A differential count showed 86 per cent polymorphonuclears, 12 per cent lymphocytes, 1 per cent eosinophils and 1 per cent monocytes. The red cells and platelets appeared normal. The blood Hinton test was negative.

During her first two days' stay in the hospital her temperature ranged from 99 to 102°F., and she complained of constant pain in the region of the right costovertebral angle. On admission, treatment consisted of a high-fluid intake and urotropin and sodium acid phosphate. Pantopon was given once a day for the control of pain. Vomiting occurred once during the first two days, and the vomitus consisted of 120 cc of dark yellow fluid containing considerable mucus. The urine output varied from 900 to 2700 cc daily, with fluid intake varying from 1800 to 3000 cc. The third day after entry cystoscopic and pyelographic studies were made. These showed the bladder to be slightly but diffusely reddened and to present no areas of ulceration. The opening of the left ureter was patent and yielded apparently clear urine. A No. 6 catheter readily passed to the right kidney, and there was a flow of clear urine. A right-sided pyelogram showed the catheter to extend into the kidney pelvis. The minor calices appeared dilated, but the pelvis was normal in size. The ureter just below the pelvis appeared dilated. Both kidney outlines were obscured by

gas in the large bowel. The injected right kidney was normal in position.

A physical examination performed by a second physician showed findings similar to those first described and, in addition, a mass in the right upper quadrant which was tender on inspiration. There was more tenderness in the right flank than in the left, and this was present both anteriorly and posteriorly. On the fifth day after admission her

Figure 1 Retrograde Pyelogram of the Left Kidney

temperature fell to normal and did not go above 99°F for a period of four days, at which time it rose to 101°F and remained between this point and 99°F for the remainder of her stay. A Graham test done on the fifth day after admission was negative. A single film of the chest, with fluoroscopy, showed the right leaf of the diaphragm slightly elevated as compared with the left. Both were sharply domed and smooth in outline. Both costal angles were clear, and the diaphragmatic excursion was normal. There were several calcified areas in the right axilla and in the region of the left hilus. The lung fields were clear.

The pain in the right upper quadrant persisted, and she obtained very little relief from Pantopon and became restless and unresponsive. A non-protein nitrogen eight days after admission was 140 mg per cent. On the tenth day it was 210 mg per cent. A second pyelographic study was made, and the left ureter was catheterized, without evidence of obstruction. At first there was a flow of thin, slightly hazy urine, which in a short time changed to a discharge of pure pus. The right kidney was catheterized, and an intravenous

phenolsulfonephthalein test done. There was no dye excretion from the left kidney in about twenty-five minutes, and the amount coming from the right was too small to measure. A pyelogram of the left kidney showed dilatation and irregularity of the calices, a pelvis of normal size and a normal ureter (Fig 1). Examination of urine from the right kidney showed 3 to 10 leukocytes, no erythrocytes and 3 to 10 squamous cells per high-power field, urine from the left kidney, 10 to 20 leukocytes in occasional clumps, 3 to 10 erythrocytes and 3 to 10 squamous cells per high-power field, and the bladder specimen, numerous leukocytes in occasional clumps, 10 to 20 erythrocytes and frequent squamous cells per high-power field. Cultures of all three specimens showed *Bacillus coli*. Blood-pressure determinations were made daily after her eighth day of stay and showed a range of from 110 to 150 systolic, 70 to 100 diastolic.

Two weeks after admission the patient's restlessness increased and she soon became unresponsive and comatose. Death occurred on the fifteenth day of her hospital stay.

#### DIFFERENTIAL DIAGNOSIS

DR JAMES A. HALSTED. This record gives us the history of a forty-year-old woman whose symptoms began at the age of thirty-one, with evidence of bilateral kidney disease. The diagnosis of pyelitis was made at the onset, but she failed to improve on treatment. This suggests that there was some underlying cause for the pyelitis. A year after the onset she had an acute attack of abdominal pain, and a normal appendix was removed. The abdomen was explored, but exploration through an appendix incision does not necessarily rule out abnormalities in the kidney or gall-bladder region. At this time she had x-rays which showed calcified masses in the abdomen, probably tuberculous nodes, and abnormality of both kidney pelves. For the next eight years she had frequent attacks that appear to be typical of bilateral renal infection. The description of her pain on admission to this hospital two weeks before her death is a little more suggestive of an inflammatory process in the right upper quadrant than of her usual pain referred to the kidney. However, it did extend into the flank and she had dysuria, so that I believe it was caused by inflammation in or around the right kidney.

The past history is of interest in that she had chronic osteomyelitis of the right hip which might have been a focus for cortical abscesses or perirenal infection. The nature of the intestinal obstruction for which she had had an operation twenty years previously can only be guessed at.

It may have been due to tuberculosis in view of the x-ray evidence of healed tuberculous lymph nodes. Of possible significance is the fact that only one pregnancy had occurred, resulting in a stillbirth. Her chronic kidney disease may have been the cause for this.

The physical examination showed a patient with fever, agonizing pain and restlessness. There was a tender mass in the right upper quadrant, with spasm and tenderness in the right flank, and the diaphragm was higher than normal on the right.

The laboratory studies showed that there were pyuria, hematuria and marked leukocytosis. There was marked nitrogen retention, and practically no phenolsulfonephthalein excretion. Thus she had infected kidneys with renal insufficiency. It is of some interest that there was no hypertension, in fact the blood pressure tended to be abnormally low. In view of the evidence of calcified tuberculous nodes, one might venture the suggestion that she had Addison's disease, but I think the low blood pressure was due to the fact that she was extremely sick. Her course in the hospital was one of sepsis and uremia, progressing to death.

Will Dr Morrison now show us the x-rays?

DR SIDNEY L. MORRISON. As you see, there is a very marked curvature of the spine. These two films show the left kidney, while this one shows the right. The outlines of the kidneys are very indistinct and of bizarre arrangement, with dilatation of the calices on both sides. The right kidney is enlarged if this indistinct line is correctly interpreted as kidney margin.

DR HALSTED. Would you say there was any dilatation from ureteral obstruction?

DR MORRISON. I would not say it was ureteral obstruction because there is no evidence of ureteral dilatation and the catheter has gone up to each kidney.

DR HALSTED. Do you think the x-ray findings are consistent with polycystic kidneys?

DR MORRISON. I do.

DR HALSTED. It seems to me that the x-ray examinations in this case are of extreme importance in giving a lead as to the background for her chronic renal infection. In the differential diagnosis one must consider the following conditions. First of all, could this be obstruction as a result of stones, kinks or aberrant vessels? I do not believe it could be because the x-ray films should show more marked evidence of hydronephrosis at this stage, when she obviously had practically no functioning kidney tissue left. So I think we can rule out obstruction as a cause for her renal failure. Could the osteomyelitis have anything to do with it, such as being a focus for cortical abscesses and perinephric abscess? I should doubt it because the process is

too diffuse and of too long a duration. Could this be a tumor? Here again I think the duration is too long, and the process is bilateral, which would be very unusual. Next we come to the possibility of its being renal tuberculosis. We are fairly sure that she has had tuberculosis, as evidenced by the calcified nodes. However, the condition clinically and by x-ray soon after the onset eight years ago showed evidence of bilateral disease. Tuberculosis of the kidney practically always begins on one side, but later on may involve both kidneys. I do not know much about renal tuberculosis, but I should say that it usually does not terminate in uremia. Furthermore, she had a *B. coli* infection, which is an infrequent, though not impossible, finding with tuberculosis of the kidney. There is also liable to be more hematuria than she had.

Could this be simple chronic pyelonephritis? Certainly it could be, and without the x-ray pictures I should be forced to make that diagnosis. However, with these films I believe it is justifiable to go a step farther and make the diagnosis of congenital polycystic kidneys. One of the plates is typical, with a crescent-shaped calyx as a result of pressure from a cyst. The clinical course is entirely consistent with this condition. Patients with polycystic kidneys generally die in the fourth decade, which this patient did. They not infrequently have a significant degree of urinary infection. Characteristically they have bilateral palpable masses, which she did not have, but that does not rule out the diagnosis because we do not know how easy it was to examine her abdomen because of the tenderness and spasm. Furthermore, I do not believe the negative abdominal exploration nine years ago through an appendix incision ruled it out. Unless the kidneys were fairly large they would not have been felt. This is a fairly rare condition, but because of this characteristic x-ray picture I believe it was the background for secondary renal infection, with perinephric abscess from direct extension and death from uremia.

DR FRANKLIN G. BALCH, JR. Is pyelonephritis a common complication of polycystic kidneys?

DR. HALSTED. In one paper reviewing 60 cases, infection occurred in 50 per cent and was of serious nature in 35 per cent.

#### CLINICAL DIAGNOSES

Pyonephrosis, left  
Pyelonephritis, right  
Old osteomyelitis, right hip

#### DR. HALSTED'S DIAGNOSES

Congenital polycystic kidneys  
Pyelonephritis  
Perinephric abscess, right  
Uremia  
Healed tuberculosis of lymph nodes

#### ANATOMICAL DIAGNOSES

Congenital polycystic kidneys  
Pyelonephritis  
Perinephric abscess, right  
Bronchopneumonia  
Congenital cysts of liver  
Old osteomyelitis, right femur  
Cardiac hypertrophy  
Calcified axillary and iliac lymph nodes

#### PATHOLOGICAL DISCUSSION

DR. J. BEACH HAZARD. The autopsy findings were in complete agreement with Dr. Halsted's diagnoses. Both kidneys were markedly enlarged and increased in weight to 860 and 790 gm respectively, and presented the numerous thin-walled cysts typical of congenital polycystic kidneys. These cystic structures contained clear fluid, bloody fluid or purulent exudate. A perinephric abscess was present on the right. The heart showed moderate hypertrophy of the left ventricular wall, suggesting a precedent elevation of blood pressure. Three congenital cysts, 1 to 2 cm in diameter, filled with clear fluid, were present in the right lobe of the liver. Calcified lymph nodes in the axilla and iliac regions presented no active process to identify the etiologic agent. There was an old osteomyelitis of the right femur.

DR. HALSTED. Were the adrenal glands normal?

DR. HAZARD. Yes.

DR. GORDON MORRISON. What was the etiology of the perinephric abscess?

DR. HAZARD. This was caused by perforation of an infected cyst into the perinephric fat tissue.

## REPORT ON MEDICAL PROGRESS

## SYPHILIS

C GUY LANE, M D \*

BOSTON

GREATER strides have been made in the field of public-health work related to syphilis during the past two years than at any other comparable period of time in the history of the disease. Much of this effort has been directed toward bringing syphilis into the light of day, and teaching the population to realize that facing the problem exactly as one faces that of other infections will carry the fight farther than any other factor. Removal of the stigma of "social disease" is most difficult after centuries of custom, and this will not be accomplished for at least a generation. Meanwhile, emphasis on the need of early diagnosis and treatment, and on the great proportion of satisfactory results obtained by such management, cannot be too widely publicized.

The medical profession itself must not be forgotten, and some of its shortcomings need remedial action in order to further the cause. Many capable practitioners do not care to handle syphilis, or minimize the importance of adequate therapy. Others have not had an opportunity to become well acquainted with the disease and its care. Educational programs have for these reasons been undertaken by the majority of state societies, in the hope of bringing at least basic knowledge within the range of all. State-wide control programs have been inaugurated in many states and consultation services provided.

The cost of treatment for syphilis has in the past kept many patients from receiving proper care. This situation has been remedied to a large extent in many communities by the subsidization of clinics with state or federal funds. Where clinics are not available, the furnishing of free drugs to the physician leaves little excuse for neglect. Arrangements have been made through some county units for all cases to be treated regardless of economic status. Physicians in Massachusetts should not hesitate to avail themselves of the follow up service provided by the State Department of Public Health for tracing cases in need of active therapy and for locating contacts who may be infected. Syphilis can never be controlled so long as patients capable of transmitting the disease are not treated. This is a corollary to the fact that early and adequate therapy can wipe

out late cases in all but a gratifyingly low percentage. Contingent upon such a statement is the premise that the proper determination of cure requires lifelong observation.

Varying percentages on the incidence of syphilis among numerous population groups show wide discrepancies and have given rise to considerable disagreement. The statement that the incidence of the disease in the nation is close to 10 per cent may seem extreme, especially in rural practice, except for certain localities in the South. However, Vonderlehr and Usilton,<sup>1</sup> of the United States Public Health Service, have shown statistically that one person in every ten faces the probability of acquiring syphilis at some time during his span of life. This percentage, they show, is not indicated by routine checks under laws requiring physical examination before the issuance of a marriage license, or those made in industrial groups, or in general practice or any random population group, for several valid reasons. First, many persons have not yet acquired syphilis but are still in danger. Secondly, some patients who have had the disease give negative serological reactions and physical examinations because of treatment, while others who have been infected recover without treatment. Finally, a high percentage of cases have been removed from any given group by death. These authors further show that the results of better follow-ups indicate an encouraging decrease in the probability of disastrous outcome in adequately treated syphilis.

Studies conducted by the Co-operative Clinical Group have stressed the importance of being absolutely certain of the diagnosis before commencing treatment for syphilis. It is held to be at least as great a mistake to treat a patient for syphilis who does not have it as to fail to carry out adequate therapy when a person is infected and requires therapy. Treating a patient for syphilis in the face of an unsubstantiated clinical diagnosis, equivocal serological reports without confirmatory physical evidence and the principle of anti-syphilitic therapy "when nothing else works" are deprecated under all circumstances by the group. It has shown that an accurate diagnosis can be made only through the intelligent use of efficient and accurate laboratory aids such as dark-field examinations, routine blood tests, spinal-

Lecturer on dermatology and syphilology Harvard Medical School  
chief Department of Dermatology Massachusetts General Hospital

fluid study where indicated and x-ray and fluoroscopic heart examinations, with an evaluation of all findings in the light of the history and physical examination. The probability of future damage will then be estimable, and the course of therapy will be indicated. If these principles are applied to a sufficiently large percentage of existing cases, it is asserted the disease may come under control, from a public-health standpoint, within a decade.

Studies of blood serological sensitivity and specificity have continued, and new or modified tests appear from time to time. At present any test which is less than 99 per cent specific and 65 per cent sensitive to syphilis is not satisfactory. The Hinton test done at the Wassermann Laboratory in Massachusetts fulfills these requirements. The policy of reporting blood tests as positive, doubtful or negative is advisable, since quantitative serological tests have not as yet been developed to the point where they are suitable for general use. In addition to this, they could not even then be used as a guide to treatment. The more rapid micro-precipitation tests are of great value under circumstances such as the testing of donors, but must be performed by skilled technicians. The advisability of having two or more tests done, preferably of different types and in different laboratories, cannot be overlooked.

New rapid blood tests which are proposed for the general use of the practitioner as simple, inexpensive, rapid and accurate, and as requiring no special technical training for their employment, should be accepted with reservations, especially if offered on a commercial basis. Studies have shown that such tests require considerable training and experience if they are to yield reliable results. But they may be quite comparable to the established tests if carried out as controlled laboratory procedures by competent technicians. There is at present no test for general use which is rapid, accurate, reliable, inexpensive and simple.

It is known that leprosy frequently causes a positive reaction in blood serological tests for syphilis, a few diseases of commoner occurrence in this country have been said to do so in a lesser percentage of cases. Malaria is perhaps the most notable of these, and an interesting study of the disease in this connection has been reported by Hazen and his co-workers<sup>2</sup> who studied 266 patients with no history or physical evidence of syphilis by means of the Hinton, Kline and Kolmer tests. Hazen quotes other authorities in order to show that malaria may act as a provocative agent in bringing a reagin of low titer up to the threshold where fixation of the complement becomes obvious in the tests. He concludes, how-

ever, that malaria can be the cause of positive serological reactions to tests for syphilis.

Encouraging progress has been made in the field of spirochete stains for both tissue sections and direct smears from open lesions. These methods are being simplified and speeded up by various modifications, so that we may hope that they will prove practicable in the not too distant future. Such stains would be of great value in early cases where we now rely on dark-field examinations.

The value of studying patients with urologic disease for syphilis has been brought out by Friedman and Mazer.<sup>3</sup> An unselected group of 252 such patients were questioned as to the history of syphilis and were examined in a cursory manner, unless findings indicated more investigation, and blood tests were done three times at monthly intervals. Seventy-three patients (29 per cent) were found to have syphilis. The value of such work lies in the finding of new and unknown syphilis and previously undertreated cases.

Wile<sup>4</sup> emphasizes the part that syphilis may play in surgery. He believes that there is little risk to the operator if an accidentally infected wound is made to bleed freely and is immediately treated with strong calomel ointment. In patients with syphilis of long standing there is no danger to the operator if the patient has been adequately treated. The patient's benefit from surgery is seriously endangered in active syphilis, as sites of surgical procedures are ideal foci for acute syphilomas. Old cases previously well treated are good risks, but in untreated cases several weeks of fairly intensive therapy should precede the surgery, and treatment should be continued through convalescence.

A study of the infectiousness of the semen of patients with late syphilis has been carried out by Kemp,<sup>5</sup> who summarizes the reports in the literature and adds 15 animal inoculation cases of his own. His conclusions are that spirochetes are present in the semen of early cases in about the same percentage as in the other body fluids. There is no adequate reason for belief in the infectiousness of the semen of patients with late syphilis.

Persistent emphasis on the extreme importance of the continuous method of therapy in early syphilis, in contradistinction to the intermittent plan, is the theme of numerous reports. Enough evidence has accumulated to make continuous therapy a routine procedure. There is also no doubt that patients who neglect their treatment may be considered to have been handled on the intermittent plan and thus to have decreased their chances of satisfactory outcome.

Studies of various drugs used in the treatment

of syphilis have continued. Further experiences with Mapharsen by various observers indicate that it is satisfactory, and is comparable to the arsphenamines for routine employment. The lower degree of toxic manifestations makes it more desirable in many cases. The use of Mapharsen has not shown it to be more efficacious than the other arsenicals for serofast cases, as was previously claimed.

Several new arsenicals have been studied, of both trivalent and pentavalent type. So far these have proved of less value than already established drugs, or have been subjected to a trial insufficient to warrant their general acceptance. This should serve as a warning to physicians against any such new product, whether urged upon them through mail advertising or in direct solicitation by drug salesmen.

Considerable literature has appeared on the oral administration of bismuth, and commercial propaganda has been prominent, but more data as to its ultimate value are required before it can be recommended. Oral therapy is certainly as much to be desired for syphilis as for diabetes and numerous other maladies, but in so grave a situation we cannot be too exacting in our demands for adequate scientific proof of the efficacy of the compounds advocated. The conclusions of the most competent investigators are, however, that the oral administration of bismuth merely justifies more extended and controlled clinical trial. Pains-taking experimental research and prolonged, rigidly controlled clinical study, concerning late as well as immediate effects, are necessary before such agents can be accepted. The newer drugs do not as yet meet these requirements, and when they do, the fact will be made known through medical publications, not through detail men.

Continued studies on the absorption and excretion of bismuth given intramuscularly indicate that the oily suspensions of insoluble salts and some of the oil-soluble products are the best vehicles for routine use. It is necessary to administer the drug often enough to maintain a constant effective level in the blood stream. This is measured accurately and conveniently by means of a recently developed rapid method for the estimation of the excretion of bismuth in the urine, which reflects the blood content. Oil suspensions of bismuth may be administered in suitable weekly doses, and oil-soluble preparations in bi-weekly doses, both these provide a slowly attained but sustained level of the metal in the blood stream. Aqueous or ethylene-glycol solutions give a more rapid effect, but are excreted so quickly that they must be injected three times weekly.

The use of mercury in the management of syphilis should not be forgotten. This is emphasized by Wright,<sup>6</sup> who places the relative effectiveness of arsenic, bismuth and mercury in the treatment of syphilis in the ratio of 10 : 7 : 4. He summarizes the indications for mercury as follows: for cases intolerant to arsenic or bismuth or both, as an alternate drug when the patient is saturated with arsenic and bismuth, in syphilis resistant to arsenic and bismuth, for recurrences after the use of arsenic and bismuth, as an alternate drug in serofast syphilis, for the reinforcement of arsenic and bismuth, in ocular syphilis, in visceral syphilis, in involvement of the central nervous system, and for certain congenital cases. These statements do not apply to oral administration.

Fever therapy in early syphilis, alone or combined with chemotherapy, should be regarded as strictly experimental. It seems to intensify the curative action of chemotherapeutic agents, and in time some combination of the two modes may be worked out. At present, however, such a technic should not be routinely applied to early syphilis.

The investigation of fever therapy for syphilis is being constantly extended, and this method is now well accepted, after a thorough trial of chemical agents has been applied, in the following manifestations of the disease: syphilis of the central nervous system, interstitial keratitis, resistant cutaneous or osseous involvement, and, occasionally, relapsing early syphilis. Fever therapy has been found to be of no material value in latent syphilis, cardiovascular syphilis, syphilis involving the liver or stomach and late syphilis of the mucous membranes. When satisfactory response to fever occurs, it is assumed that such results are due to some fundamental change in the immunologic processes of the body, the nature of which is still unknown. The utmost care is necessary in the selection of patients as satisfactory risks. The method of production of fever, among the many advocated, which will give the most gratifying response, with the most prolonged maintenance of results and the least harmful side actions, has not yet been ascertained. Many years of study of end results will be required in order to determine the most satisfactory method.

The possibility of syphilis in pregnancy must be kept constantly in mind if there is to be a reduction of the number of innocent victims of the congenital form of the disease. Congenital syphilis is preventable, and with adequate co-operation of the public and the medical profession it can be eliminated. Conservative opinion today holds that every woman who has ever been diagnosed as syphilitic should have some active treatment dur-

ing every subsequent pregnancy, regardless of the status of her serological test or the extent of previous therapy. In this connection it must be borne in mind that one negative blood test in pregnancy may not reflect the true status of past or suspected syphilis. The effect of the arsphenamines on the fetus has been studied recently by Vamos and Böhm.<sup>7</sup> The only way to protect the fetus, they assert, is to immunize the mother thoroughly, and thus the fetus indirectly. This fact again proves the extreme importance of energetic treatment of the infected mother before and throughout pregnancy.

In all infants born of syphilitic mothers, all authorities agree that the diagnosis must be proved as surely as in acquired syphilis. Where there is reason to suspect the disease and the first investigations are negative, diagnostic procedures should be repeated at monthly intervals, and later less often, for several years. No offspring of a mother in any stage of syphilis, "cured" or not, should be discharged until after several years of adequate follow up. Once the diagnosis of syphilis has been established, it must be remembered that no infant is too young to receive active arsenical and heavy-metal therapy in appropriate doses.

Tertiary asymptomatic syphilis provides our most delicate problems of therapy. Individualization of cases here becomes especially necessary. Three types of cure may be considered: biologic cure, which is in all probability seldom if ever attained; serologic cure, which is of course desirable but not always essential; and symptomatic cure, whereby the patient becomes and remains non-infectious and well, so far as syphilis is concerned, for the duration of his life. In these so-called latent cases it is not always advisable to begin immediate treatment. Study of the entire medical status of the patient is indicated, with consideration of any other disease he may have, and judgment as to whether anti-syphilitic therapy may aggravate existing conditions. The problems of immunity in regard to treatment have given rise to considerable discussion. Kolmer<sup>8</sup> has covered this phase of syphilis in a well planned series of animal and human studies. Among other problems he considers the question whether positive serology in an apparently healthy patient with previous adequate therapy always means the persistence of syphilitic infection and also whether this state requires further treatment. Kolmer believes it possible that the acquired immunity of syphilis is responsible for clinical latency but that this immunity cannot be relied upon alone to maintain latency indefinitely or to provide complete recovery without the aid of modern treatment. Serological relapse is thus interpreted as

an indication of the renewed activity of foci of infection. Kolmer holds it wise to give periodic follow-up therapy in these cases, not in order to reverse the serological reactions, but as an aid to immunity in preventing relapse or progression of the disease. He applies the same principle to asymptomatic latent acquired or congenital patients who have completed their routine treatment, varying the follow-up therapy in accordance with the physical and serological status of the patient. This treatise is worthy of careful study in full.

In cardiovascular syphilis, one of the most fruitful recent reports is that of Wile and Snow<sup>9</sup> on the asymptomatic group. In a third of 210 cases of uncomplicated aortitis, aortic insufficiency and aneurysm they found the disease to be symptomatically occult. In addition, a fair percentage of the patients were devoid of any clinical evidence of cardiovascular involvement. It is emphasized that during the period of latency the cardiovascular system should be under constant suspicion, and that the significance of the most minor symptoms or findings should be thoroughly investigated. In x-ray diagnosis it has been brought out by Padgett and Moore<sup>10</sup> that the left anterior oblique position for teleroentgenography, preceded and supplemented by fluoroscopy, seems the most promising method of examination and should be further elaborated.

The most informative report on syphilis of the central nervous system to be recently published is that of the Co-operative Clinical Group<sup>11</sup> on tabes dorsalis. Nine hundred and eighty-five cases formed the basis for this report. It is a long and comprehensive study which merits thorough perusal. The blood Wassermann test was found to be an inefficient guide in the diagnosis or treatment of tabes, being negative in 32 per cent of the cases with a positive spinal fluid. The degree of positivity of the spinal fluid allowed a fairly accurate estimation of the prognosis and proved a fair guide as to the type of therapy needed. The disease may progress clinically even with a negative spinal fluid. Improvement in the spinal fluid more often preceded clinical response, but the latter did not always take place after the fluid became negative. Routine chemotherapy brought about a response in the spinal fluids of 29 per cent of 396 cases in which this method alone was employed. (Note that this is not 29 per cent of the entire group studied.) A combination of routine chemotherapy, intraspinal injection and malaria brought about a response in the shortest space of time. Routine treatment plus tryparsamide was the slowest method. Artificial methods of inducing fever had not been introduced at the time this study was begun. Routine treatment with arsenic

of syphilis have continued. Further experiences with Mapharsen by various observers indicate that it is satisfactory, and is comparable to the arsphenamines for routine employment. The lower degree of toxic manifestations makes it more desirable in many cases. The use of Mapharsen has not shown it to be more efficacious than the other arsenicals for serofast cases, as was previously claimed.

Several new arsenicals have been studied, of both trivalent and pentavalent type. So far these have proved of less value than already established drugs, or have been subjected to a trial insufficient to warrant their general acceptance. This should serve as a warning to physicians against any such new product, whether urged upon them through mail advertising or in direct solicitation by drug salesmen.

Considerable literature has appeared on the oral administration of bismuth, and commercial propaganda has been prominent, but more data as to its ultimate value are required before it can be recommended. Oral therapy is certainly as much to be desired for syphilis as for diabetes and numerous other maladies, but in so grave a situation we cannot be too exacting in our demands for adequate scientific proof of the efficacy of the compounds advocated. The conclusions of the most competent investigators are, however, that the oral administration of bismuth merely justifies more extended and controlled clinical trial. Pains-taking experimental research and prolonged, rigidly controlled clinical study, concerning late as well as immediate effects, are necessary before such agents can be accepted. The newer drugs do not as yet meet these requirements, and when they do, the fact will be made known through medical publications, not through detail men.

Continued studies on the absorption and excretion of bismuth given intramuscularly indicate that the oily suspensions of insoluble salts and some of the oil-soluble products are the best vehicles for routine use. It is necessary to administer the drug often enough to maintain a constant effective level in the blood stream. This is measured accurately and conveniently by means of a recently developed rapid method for the estimation of the excretion of bismuth in the urine, which reflects the blood content. Oil suspensions of bismuth may be administered in suitable weekly doses, and oil-soluble preparations in bi-weekly doses, both these provide a slowly attained but sustained level of the metal in the blood stream. Aqueous or ethylene-glycol solutions give a more rapid effect, but are excreted so quickly that they must be injected three times weekly.

The use of mercury in the management of syphilis should not be forgotten. This is emphasized by Wright,<sup>6</sup> who places the relative effectiveness of arsenic, bismuth and mercury in the treatment of syphilis in the ratio of 10 : 7 : 4. He summarizes the indications for mercury as follows: for cases intolerant to arsenic or bismuth or both, as an alternate drug when the patient is saturated with arsenic and bismuth, in syphilis resistant to arsenic and bismuth, for recurrences after the use of arsenic and bismuth, as an alternate drug in serofast syphilis, for the reinforcement of arsenic and bismuth, in ocular syphilis, in visceral syphilis, in involvement of the central nervous system, and for certain congenital cases. These statements do not apply to oral administration.

Fever therapy in early syphilis, alone or combined with chemotherapy, should be regarded as strictly experimental. It seems to intensify the curative action of chemotherapeutic agents, and in time some combination of the two modes may be worked out. At present, however, such a technic should not be routinely applied to early syphilis.

The investigation of fever therapy for syphilis is being constantly extended, and this method is now well accepted, after a thorough trial of chemical agents has been applied, in the following manifestations of the disease: syphilis of the central nervous system, interstitial keratitis, resistant cutaneous or osseous involvement, and, occasionally, relapsing early syphilis. Fever therapy has been found to be of no material value in latent syphilis, cardiovascular syphilis, syphilis involving the liver or stomach and late syphilis of the mucous membranes. When satisfactory response to fever occurs it is assumed that such results are due to some fundamental change in the immunologic processes of the body, the nature of which is still unknown. The utmost care is necessary in the selection of patients as satisfactory risks. The method of production of fever, among the many advocated, which will give the most gratifying response, with the most prolonged maintenance of results and the least harmful side actions, has not yet been ascertained. Many years of study of end results will be required in order to determine the most satisfactory method.

The possibility of syphilis in pregnancy must be kept constantly in mind if there is to be a reduction of the number of innocent victims of the congenital form of the disease. Congenital syphilis is preventable, and with adequate co-operation of the public and the medical profession it can be eliminated. Conservative opinion today holds that every woman who has ever been diagnosed as syphilitic should have some active treatment dur-

ing every subsequent pregnancy, regardless of the status of her serological test or the extent of previous therapy. In this connection it must be borne in mind that one negative blood test in pregnancy may not reflect the true status of past or suspected syphilis. The effect of the arsphenamines on the fetus has been studied recently by Vamos and Böhm.<sup>7</sup> The only way to protect the fetus, they assert, is to immunize the mother thoroughly, and thus the fetus indirectly. This fact again proves the extreme importance of energetic treatment of the infected mother before and throughout pregnancy.

In all infants born of syphilitic mothers, all authorities agree that the diagnosis must be proved as surely as in acquired syphilis. Where there is reason to suspect the disease and the first investigations are negative, diagnostic procedures should be repeated at monthly intervals, and later less often, for several years. No offspring of a mother in any stage of syphilis, "cured" or not, should be discharged until after several years of adequate follow up. Once the diagnosis of syphilis has been established, it must be remembered that no infant is too young to receive active arsenical and heavy-metal therapy in appropriate doses.

Tertiary asymptomatic syphilis provides our most delicate problems of therapy. Individualization of cases here becomes especially necessary. Three types of cure may be considered: biologic cure, which is in all probability seldom if ever attained, serologic cure, which is of course desirable but not always essential, and symptomatic cure, whereby the patient becomes and remains non-infectious and well, so far as syphilis is concerned, for the duration of his life. In these so-called latent cases it is not always advisable to begin immediate treatment. Study of the entire medical status of the patient is indicated, with consideration of any other disease he may have, and judgment as to whether anti-syphilitic therapy may aggravate existing conditions. The problems of immunity in regard to treatment have given rise to considerable discussion. Kolmer<sup>8</sup> has covered this phase of syphilis in a well planned series of animal and human studies. Among other problems he considers the question whether positive serology in an apparently healthy patient with previous adequate therapy always means the persistence of syphilitic infection, and also whether this state requires further treatment. Kolmer believes it possible that the acquired immunity of syphilis is responsible for clinical latency but that this immunity cannot be relied upon alone to maintain latency indefinitely or to provide complete recovery without the aid of modern treatment. Serological relapse is thus interpreted as

an indication of the renewed activity of foci of infection. Kolmer holds it wise to give periodic follow-up therapy in these cases, not in order to reverse the serological reactions, but as an aid to immunity in preventing relapse or progression of the disease. He applies the same principle to asymptomatic latent acquired or congenital patients who have completed their routine treatment, varying the follow-up therapy in accordance with the physical and serological status of the patient. This treatise is worthy of careful study in full.

In cardiovascular syphilis, one of the most fruitful recent reports is that of Wile and Snow<sup>9</sup> on the asymptomatic group. In a third of 210 cases of uncomplicated aortitis, aortic insufficiency and aneurysm they found the disease to be symptomatically occult. In addition, a fair percentage of the patients were devoid of any clinical evidence of cardiovascular involvement. It is emphasized that during the period of latency the cardiovascular system should be under constant suspicion, and that the significance of the most minor symptoms or findings should be thoroughly investigated. In x-ray diagnosis it has been brought out by Padgett and Moore<sup>10</sup> that the left anterior oblique position for teleroentgenography, preceded and supplemented by fluoroscopy, seems the most promising method of examination and should be further elaborated.

The most informative report on syphilis of the central nervous system to be recently published is that of the Co-operative Clinical Group<sup>11</sup> on *tabes dorsalis*. Nine hundred and eighty-five cases formed the basis for this report. It is a long and comprehensive study which merits thorough perusal. The blood Wassermann test was found to be an inefficient guide in the diagnosis or treatment of *tabes*, being negative in 32 per cent of the cases with a positive spinal fluid. The degree of positivity of the spinal fluid allowed a fairly accurate estimation of the prognosis and proved a fair guide as to the type of therapy needed. The disease may progress clinically even with a negative spinal fluid. Improvement in the spinal fluid more often preceded clinical response, but the latter did not always take place after the fluid became negative. Routine chemotherapy brought about a response in the spinal fluids of 29 per cent of 396 cases in which this method alone was employed. (Note that this is not 29 per cent of the entire group studied.) A combination of routine chemotherapy, intraspinal injection and malaria brought about a response in the shortest space of time. Routine treatment plus tryparsamide was the slowest method. Artificial methods of inducing fever had not been introduced at the time this study was begun. Routine treatment with arsenic

and blamash was recommended for not over one year, to be followed by supplementary methods at the end of that time if the spinal fluid was not responding, or sooner if the routine therapy was found inadequate to stop progression. The same applied to symptomatic response. The clinical results were likewise calculated the conclusion being that a combination of routine plus intraspinal or caliche therapy was the most satisfactory method. Trypanamide was helpful but of less value in stopping active progression of the disease. Fourteen per cent of the cases progressed in spite of treatment. Intraspinal therapy was more effective than other complementary modes, regardless of the stage of the case at the start of treatment, even if more such treatments were required. Diplopia gave the best response and optic atrophy the poorest. It was brought out that no accurate estimate of the value of any treatment program can be made for tuber dorsalis until the incidence of cases is known in which the symptoms of the disease disappear spontaneously as well as those which progress to the end point.

A controversy has been going on as to whether a negative blood Hinton indicates a negative spinal fluid. Margolis<sup>11</sup> has added some data for consideration, in a study of 511 cases. Among these were 172 positive spinal fluids, of which 11 showed negative blood Hinton tests. All these patients and considerable clinical evidence of injury to the central nervous system. Margolis therefore concludes that asymptomatic neurosyphilis associated with a persistently negative blood Hinton must be rare, and that routine spinal fluid may be omitted in patients with no clinical evidence of the central nervous system and a persistently negative

blood Hinton reaction. However, this subject cannot yet be considered closed.

Numerous reports are available on complications occurring during antisyphilitic therapy, but cannot be discussed here. Some of the more interesting of these include liver damage following arsenical therapy,<sup>12,13</sup> dermatitis due to antimonials,<sup>14</sup> hematopoietic depression<sup>15</sup> and the role played by vitamin C.<sup>16</sup>

I am indebted to Dr. G. Marshall Carter for assistance in preparing this report.

### CASE 25041

#### PRESENTATION OF CASE

A fifty-eight-year-old housewife was admitted complaining of postmenopausal vaginal bleeding.

Two and a half years before admission she had been examined and curetted at an outside hospital for vaginal bleeding. The pathological examination showed no evidence of cancer. The bleeding continued as bright-red blood, and she had required a pad ever since that time. Two weeks before entry she began having chills, fever and local tenderness in the lower abdomen, with the passage of a profuse, saffron-colored, watery, vaginal discharge. A palpable, tender mass was noticed in the left lower abdomen. Since that time there had been no passage of blood. She had no gastrointestinal or urinary symptoms, or no gain or loss of weight. Years ago she had had a fallopian tube, an ovary and the appendix removed.

Physical examination showed an obese woman, with tenderness and spasm in the left lower abdomen. The head and chest were negative. The breasts showed evidence of cystic mastitis. The blood pressure was 134 systolic, 78 diastolic. In the left lower quadrant of the abdomen there was a large, soft, somewhat irregular mass about 10 cm in diameter, which extended to the midline. Pelvic examination showed an essentially normal cervix. The right vault was fuller than the left, and a fluid wave was elicited in ballotting the mass between the left lower abdomen and the examining finger. The mass was possibly continuous with the uterus.

The temperature was 102°F, the pulse 100, the respirations 28.

The urine examination was negative, except for the presence of 20 to 30 white cells per high-power field. The blood showed 65 per cent hemoglobin and a white-cell count of 14,500. The sedimentation rate was 1.3 mm per minute.

Under ether anesthesia another vaginal examination was performed. A large, smooth, rounded mass could be felt occupying the left vault and extending halfway to the umbilicus. It was definitely cystic and seemed adherent behind a small, atrophic uterus.

Following this examination an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. GEORGE VAN S. SMITH: \* As is very often true in gynecological cases, one cannot commit oneself unequivocally to a single diagnosis here, for the data presented lend themselves to explanation by a variety of pathologic entities.

I feel justified in dismissing at once from consideration, first, the patient's cystic mastitis—because of our lack of knowledge of any causal relation between pelvic disease and this disease, secondly, carcinoma of the vagina or cervix—on the basis of examination, and thirdly, all benign causes of uterine bleeding—because it is practically axiomatic that benign processes rarely produce persistent, unmodified, bright-red bleeding before the menopause, and never after the menopause—with the possible exception of benign granulosa-cell tumors. Even with a granulosa-cell tumor I should expect a history at least suggestive of some periodicity of flow and of blood at times more or less like that of menstruation. Furthermore, against granulosa-cell tumor are the small uterus, indicating absence of prolonged estrogenic stimulation, and the negative pathological report on the original curettage. If there had been real hyperplastic endometrium due to granulosa-cell tumor, the report would probably have hedged on the possibility of cancer. Two and a half years of bleeding from a uterus that is still small and atrophic makes cancer of the endometrium only a remote guess. Thus far I have concluded that cancer was the cause of this patient's flowing and that it was not in the uterine cavity.

If a patient presents herself complaining of postmenopausal bleeding and if careful examinations with biopsies fail to reveal the cause, we have found it safer to proceed with abdominal exploration immediately after recurrence of the bleeding. In such a case we expect to find one of the following four conditions: adenocarcinoma in the myometrium, primary in an area of adenomyoma, primary carcinoma of a fallopian tube, primary carcinoma of an ovary, with involvement of tube or uterine wall or both, or metastatic tumor. These may cause bleeding from the uterus without yielding any palpable or biopsy evidence of their presence.

From the history and general examination, metastatic tumor may be ruled out. Again, because of the small uterus, cancer in the myometrium with cystic involvement of the ovary is improbable.

\* Visiting surgeon, Free Hospital for Women, Brookline, Massachusetts; instructor in gynecology, Harvard Medical School.

Her loss of a tube and ovary years ago suggests that she had had a conservative operation for pelvic inflammation. Since the cystic mass of her present illness was on the left, I presume that the left adnexa had been saved.

At this point I picture the following course of events: a left tubo-ovarian abscess years ago resulting in a tubo-ovarian cyst, later, development of cancer of the tube or ovary with bleeding into the uterus, and, finally, an acute inflammatory exacerbation, with rupture of a septum in the ovary and escape of yellowish, watery material through the tube and uterus.

It hardly seems likely that the acute inflammation which precipitated her entry to the hospital could have been due to retrograde infection through the uterus, especially when it was apparently draining the tube satisfactorily. Furthermore, chills and a fever of 102°F seem more than would be expected in such a chronic situation. I should rather incriminate the bowel as the source of this infection—adhesions between the sigmoid and the tubo-ovarian cyst, diverticulum, and acute inflammation with increase in the size of the cyst and in tension, resulting in escape of fluid through a tube containing a primary cancer, which may also have involved the ovary. I suspect that the post-operative course was stormy.

DR. JOE V. MEIGS: How frequently do you see carcinoma of the tube in your hospital?

DR. SMITH: We have seen at least 5 cases, 2 in the past year.

DR. LANGDON PARSONS: That is interesting because we apparently never had a proved carcinoma of the tube in this hospital until 1932. People reporting now claim there is an increasing incidence of carcinoma of the tube. I believe one is justified in saying it is rare, because at the Johns Hopkins Hospital<sup>1</sup> 5 cases in a total of 35,000 have been reported, and at the Bellevue Hospital<sup>2</sup> 3 cases in a total of 30,000. I personally have seen 2 cases within a week, having seen it previously but once. Since that time Dr. Joe V. Meigs has seen 2 cases within another two weeks. That makes 4 cases within the course of a month. The impression is that the condition is rare, but the importance lies in the fact that it is a very malignant tumor. In fact it is the most malignant of all the genital tumors. There are only 7 cases recorded in the literature that have lived longer than three years. That is of considerable importance, especially if it is true that there is an increasing number of cases. We have seen only 6 cases in this hospital, and 2 at the Pondville Hospital.

So far as we can find out from the literature the train of events is very similar to that presented by the patient Dr. Smith has discussed. The inter-

esting thing to me is that the fimbriated end of the tube apparently closes late in the disease. Because the cancer only involves the tubular wall as a late manifestation, the early picture is one of hydrosalpinx, with which it is frequently confused. In fact one of these cases had a salpingectomy on one side, the surgeon believing that the lesion was a simple hydrosalpinx. Because of the enormous distention and thin wall, carcinoma was not suspected. Bilateral lesions are often found.

Many of these patients give a history of vaginal staining accompanied by intermittent colicky lower abdominal pain, which is relieved by a sudden vaginal discharge of pus or blood. The mechanism may well be a late closing of the fimbriated end of the tube, with sudden distention of its thin wall to form a huge hydrosalpinx. The colic arises in an attempt to extrude the necrotic contents into the uterus, with relief when this takes place. This sequence of events closely simulates an acute pelvic inflammation. It occurs often enough to be considered as a syndrome by many writers.

DR. MEIGS: I have seen 2 cases which have not shown inflammation. The first of these I operated on in New York at the Post-Graduate Hospital, the other I operated on here in Boston a year ago. In the latter patient, a mass was attached to the posterior uterine wall that felt like a fibroid. Curettage was negative. She continued to bleed, and I operated later and found the tumor. There was no inflammatory process. The 2 other cases I have seen had pelvic inflammation.

DR. PARSONS: The important diagnostic point is the finding of a negative endometrium in an atrophic uterus in a patient who is bleeding after the menopause.

#### CLINICAL DIAGNOSES

Carcinoma of the fallopian tube  
Pyometra

#### DR. SMITH'S DIAGNOSES

Carcinoma of the fallopian tube  
Tubo-ovarian abscess

#### ANATOMICAL DIAGNOSES

Papillary adenocarcinoma of the fallopian tube  
Follicular cysts of the ovary  
Tubo-ovarian abscess

#### PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: Whenever a new disease appears, one always begins to wonder as to why that disease has not been seen before. There is no question that new diseases do develop from

time to time Infectious diseases formerly limited to animals may spread to man, new processes in industry introduce new toxicologic factors, physicians themselves are only too often the culprits, and in their attempts to cure one disease, they upset a delicate balance and produce another But I do not believe that new diseases are particularly frequent or that many new forms of cancer develop Yet we begin to hear from time to time of what are to us new forms of cancer This has been borne out very strikingly in the case of cancer of the lung Up to about 1920 it was supposed that primary carcinoma of the lung was one of the rarest of all forms of pulmonary cancer Now we firmly believe it is one of the commonest No one has been able to decide with any certainty whether the number of cases has actually increased It is quite possible that it has, but it is equally possible that we are simply recognizing it where we failed before

It has always been a tradition in pathology that cancer of the fallopian tube is extremely rare, and as a result, pathologists have almost never made the diagnosis unless they could exclude all other possibilities If they found cancer limited to the tube, they might be willing to make the diagnosis, but if there was the remotest involvement of the ovary or uterus they would always say it came from one or the other of those two sources We unquestionably have missed many cases in the past by such an attitude

In this particular case I think there is very little doubt the lesion was primary in the tube If one wished to be hypercritical about it, I do not believe that we could say we are certain beyond all doubt There was involvement of the ovary, and it is conceivable that the tumor started there On the other hand there was one recognizable follicular cyst left in the ovarian tissue If the tumor had started there, probably the whole ovary would have been destroyed and it is unlikely that the entire tube would have been involved from end to end and have been so elongated So in this case I think in all probability the carcinoma arose in the tube That is the diagnosis we finally made

DR MEIGS To what was the inflammation due?

DR PARSONS There was a large inflammatory cyst of the ovary which had twisted on itself behind the uterus and had stuck to the sigmoid The cyst was ruptured and removed

DR MEIGS It was adherent to the sigmoid?

DR PARSONS Yes, very definitely

DR MEIGS The patient I saw in New York had complete involvement of the left tube Both ovaries were normal in size In the right tube there was a very small tumor hanging off the fimbriated end I think it is rather striking that

both tubes were involved and both ovaries were negative

DR PARSONS According to the literature the cancer is apt to be bilateral

DR SMITH In the 2 cases that I have seen both patients had bilateral lesions

A PHYSICIAN Was postoperative radiation given in these cases?

DR PARSONS That is the one hope, of course On none of those recorded has anything been done beyond a palliative course of x-ray treatment, which was not given with any hope of cure That may be a way of prolonging the survival period

DR BENJAMIN CASTLEMAN I should like to ask Dr Smith how often he has seen ovarian cancer that involved the tube and not the endometrium That might be a differentiating point

DR SMITH I cannot recall a case where the tube was involved and not the endometrium

### CASE 25042

#### PRESENTATION OF CASE

A twenty-one-year-old, married woman was admitted complaining of frontal headaches, failing vision and vomiting

The patient had not matured mentally after the age of twelve She was described as "silly," had a morbid sexual curiosity, and began a promiscuous life, which resulted in pregnancy and childbirth at the age of fourteen Soon after this she developed pulmonary tuberculosis She entered a sanatorium three years before admission, where a diagnosis of active tuberculosis was made by x-ray, positive sputum examinations and symptoms, including weight loss, loss of appetite and night sweats During that year a left phrenectomy was done, followed by a thoracoplasty with the resection of nine ribs on the left side The following year, after a period of riotous living, she had a hemoptysis followed by collapse During the two years before entry she was confined twice in psychopathic hospitals for attempted suicide Three months before entry, while working as a waitress, she began feeling more tired and weak than usual and having frontal headaches of increasing severity Draining ears had been present intermittently since childhood, and one month before admission she had a recurrence, with earache Two weeks later her frontal headaches became constant and very severe A week before entry they became unbearable and precipitated two or three episodes of vomiting daily Her vision began failing three days before admission, equally in both

eyes During the previous three months she had had no cough, fever or night sweats, but had lost 10 pounds in weight One month before entry a sanatorium refused admission on the ground that her tuberculosis was inactive

At the age of twelve she had had an appendectomy, and at fifteen a tonsillectomy At seventeen she had had a cesarean section and unilateral salpingo-oophorectomy for her second pregnancy Her family history was noncontributory

Physical examination showed a pale, sallow, poorly nourished girl who was dazed and staring from a severe headache Co-operation was poor, the patient was somewhat confused, although she was apparently well oriented The left pupil was larger than the right, both reacted to light External ocular movements were normal She had a right homonymous hemianopsia Visual acuity was 20/50 in the right eye and "fingers at two feet" in the left Examination of the fundi showed 4 diopters of choking of the left disk, with hemorrhages and engorged veins The right disk was similar, with 2 diopters of choking There was weakness of the right lower face Left mastoid tenderness and bilateral antral tenderness were elicited There was deafness in the right ear, a whisper being heard at 2 feet, whereas in the left ear it was heard at 10 feet Air conduction was greater than bone conduction bilaterally The Weber test was positive on the right The right tympanic membrane was moderately retracted but otherwise normal, the left was normal Examination of the mouth revealed tender and bleeding gums The tongue deviated to the left Above the left clavicle there was an old phrenectomy scar A moderate amount of left thoracic scoliosis was present There was a left thoracoplasty scar, well healed, with no ribs palpable beneath it The scar overlay an area of complete dullness and absent breath sounds There were no rales in the remainder of the chest, even after coughing The heart was normal The blood pressure was 110 systolic, 68 diastolic There were healed operative scars in the right upper quadrant and left lower quadrant of the abdomen There was tenderness in both these areas, as well as in the left upper quadrant, but no masses Pelvic examination showed a red and inflamed cervix The fundus of the uterus could not be outlined, but the vaginal vaults were negative Rectal examination was negative There was weakness of the right arm, and slight weakness of the right leg All the tendon reflexes were more active on the right side than on the left, and there was a Babinski sign on the right.

The temperature was 99°F (rectally), the pulse 60, the respirations 18

The urine contained 20 to 25 white cells per high-power field The blood showed a red-cell count of 4,640,000, 80 per cent hemoglobin, and a white-cell count of 10,700 with 71 per cent polymorphonuclears A blood Hinton was negative. A lumbar puncture revealed an initial pressure of 310 mm of water The spinal fluid was clear and colorless, without cells The total protein was 19 mg per cent, the sugar 72 mg, the goldsol curve negative, and the Wassermann test negative.

X-ray films of the skull appeared normal Chest films showed the left thoracoplasty involving the upper eight ribs, but no evidence of active disease in either lung A ventriculogram showed marked symmetrical dilatation of the lateral ventricles and only a small quantity of air in the anterior aspect of the third ventricle There was no air in the fourth ventricle The area of the third ventricle appeared to be occupied by an irregular tumor which bulged into the inferior margins of both lateral ventricles but more on the left side

On the third hospital day the patient's condition seemed definitely worse Burr holes were made and the ventricles tapped, with the removal of about 30 cc of fluid which had a total protein of 6 mg per cent She then seemed slightly improved On the following day a ventriculogram was done After a diagnosis of third-ventricle tumor, a left-sided, extensive, subtemporal, osteomyoplastic decompression was done No exploration was attempted For several days her condition progressively improved On the seventeenth hospital day she was up and around, though mentally retarded X-ray therapy was begun, 1200 r being given over a period of ten days through the right lateral skull, directed to the third ventricle On the twenty-first hospital day at 5.30 p m the patient became irrational and cried out loudly at times Four hours later she suddenly became pale and went into coma Her respirations were slow, irregular and gasping, her pulse rate dropped to about 50 After treatment for shock, the ventricles were tapped, the spinal fluid gushing out under high pressure The following morning she showed improvement and was rational but in the evening became worse The ventricle was again tapped, with improvement On the thirty-first hospital day, she was discharged home to her physician Following discharge her condition remained essentially unchanged until the evening of the fourth day after discharge, at which time she passed away suddenly, being found dead by the nurse on return to the patient's room after a few moments' absence

## DIFFERENTIAL DIAGNOSIS

DR GILBERT HORRAX \* This case is a puzzle neurologically, and a very fascinating one. It is obvious that we have to do with a condition of increased intracranial pressure which may be caused by one of a variety of pathologic conditions. At least the patient had a background for various etiologic factors. In the first place, she had had active tuberculosis, and in the second place, she had led a promiscuous sexual life, giving her a fair chance for syphilis, although the spinal-fluid Wassermann was negative, as was the blood Hinton. In the third place, she had had an opportunity for an intracranial lesion from the fact that she had had running ears intermittently since childhood, with a recent exacerbation. Aside from all these factors, there is, I believe, the more probable chance that she had a true neoplasm rather than a granulomatous tumor, because in my experience large tumors of luetic or tuberculous origin are extremely rare. I do not recall having seen a tuberculoma or syphiloma in the position in which this tumor has been demonstrated by the ventriculogram, and the same is true of ordinary abscess. It is an extremely unusual place for any one of these lesions.

We have other evidence of localization besides the ventriculogram, of course, because she had a right homonymous hemianopsia and a right Babinski sign, with increased reflexes on the right, together with some weakness of the right face, arm and leg. Just what the pupillary inequality meant is problematical, but the pupils did react to light, which, if the tumor pressed very firmly on the corpora quadrigemina, should not occur. If there was marked pressure she ought to have had restriction of the ocular movements upward. It is said in the report of the ventriculogram that the tumor mass bulged more to the left than to the right, which would agree with the neurological evidence as presented. In other words, we come down to a lesion which has been demonstrated by ventriculogram to bulge from below upward into the third ventricle. This places the site of the lesion very accurately. One must comment, therefore, as to its pathologic type, and as I said, syphiloma, tuberculoma or abscess is unlikely. This brings it down to some form of true neoplasm, and in that category one has to deal with two or three possibilities.

The most interesting of these, and one which I should like to see demonstrated, is a pinealoma. I doubt that it was a pinealoma, because almost always such a tumor causes pressure on the cor-

pora quadrigemina and eye signs and symptoms result that are at variance with the normal ones described. One could possibly interpret the sexual precocity as further evidence of a pinealoma, but the strange thing about such an assumption is that the syndrome of *pubertas praecox* has never been described in a girl. The other common types of neoplasms in this situation are glioblastomas, astrocytomas and, less frequently, ependymomas. There are other possibilities, of course, but these are the most usual ones. On the evidence, my guess is that it was some form of glioma rather than a pinealoma.

DR JAMES R LINGLEY The plain films were essentially negative, except for questionably increased intracranial pressure as suggested by the convolutional markings. The sella turcica was normal in size and shape. After air injection the tumor was very well demonstrated along its anterior and superior margins. Here you can see air entering the anterior portion of the third ventricle and outlining the anterior margin of the mass lying in the posterior portion of the ventricle. Then there is pressure upward from the mass into the cavities of the lateral ventricles so that one can also outline the extent of the superior margin of the tumor. It appears to arise in the floor of the third ventricle. It is anterior to the pineal gland.

DR CHARLES S KUBIK Does the anteroposterior view show the third ventricle?

DR LINGLEY There is hardly enough air in the third ventricle to be visible in the anteroposterior view. This view does show the tumor pressing upward a little more into the left lateral ventricle than into the right.

DR HORRAX Dr Ayer, do you think there is any spread in these ventricles?

DR JAMES B AYER It seems as if there were some spread.

DR HORRAX Tumor outline perhaps?

DR AYER There is tumor in between.

DR LINGLEY It does not appear to infiltrate the septum pellucidum. It presses upward into the lateral ventricles from below.

DR AUGUSTUS A ROSE The spinal-fluid protein was 19 mg per cent.

DR AYER That is low but not significantly so.

DR HORRAX In the x-ray film the outline of the tumor looks more sharply defined than one would expect to find with a diffuse glioma. This suggests an ependymoma or craniopharyngioma. The lack of calcification, of course, is against the latter.

DR ARLIE V BOCK What about the sexual precocity?

DR HORRAX You can have sexual precocity in young individuals with cerebral tumors other than pinealomas. It occurred in one of my patients who had a glioma in the region of the third ventricle, but it has never been reported as arising from an intracranial lesion in girls.

DR AYER Was this sexual precocity or delinquency? She was delinquent in every way.

DR HORRAX I do not know, however, I should not expect this tumor to be a pinealoma for various other reasons. My first diagnosis is a gliomatous tumor of the third ventricle, but I mention ependymoma and craniopharyngioma as possibilities.

DR JAMES C WHITE Of course we did think very seriously of Dr Horrax's suggestion of pinealoma. I went over her several times to see if I could find any impairment in the upward deviation of the eyes, without success. We had thought from the x-ray films that the tumor lay in the floor of the third ventricle and infiltrated outward to the left or else pressed from outside the ventricle and bulged in. In either case we believed that it was an infiltrating glioma and, being on the left side, that it was quite inaccessible. Hence, after consultation with a good many members of the staff, only decompression and radiation were done. Three weeks after her death a very similar case came in, and having learned from this experience, we all made a correct diagnosis. Dr John S Hodgson operated, and the patient made a successful recovery.

#### CLINICAL DIAGNOSIS

Glioblastoma  
Medulloblastoma?  
Tuberculoma?

#### DR HORRAX'S DIAGNOSIS

Glioblastoma  
Ependymoma?  
Craniopharyngioma?

#### ANATOMICAL DIAGNOSES

Cholesteatoma  
Persistent thymus

#### PATHOLOGICAL DISCUSSION

DR KUBIK The tumor was a cholesteatoma or so-called "pearly tumor." The mass, measuring from 3.5 cm to 4 cm in diameter, was situated a little to the left of the midline between the optic chiasm and the cerebral peduncles. Extending upward, it displaced the third ventricle upward and to the right. The left cerebral peduncle and optic tract were both flattened by it.

These tumors have a glistening pearly appearance. They are avascular and easily broken up into flaky and irregular fragments, which have something like a cheesy consistence and, when rubbed between the fingers, feel a lot like soap. The outside of the tumor is covered with an exceedingly thin membrane lined with flat epidermal cells containing granules of keratohyaline. There are no dermal structures, such as sebaceous or sweat glands, as in dermoid cysts, which may also be found in the suprasellar region. The pearly substance consists of desquamated, flat, epithelial cells and contains a certain amount of fat and some cholesterol.

DR MALLORY One thing that the discovery of the nature of this tumor proves is that it was unquestionably present for a long period of time. I have no idea how many years it would take for a cholesteatoma of this size to develop, but they are very slow-growing and a tumor large enough to produce some symptoms may have been present even in her childhood.

DR HORRAX I believe they are congenital. Do you not think so?

DR MALLORY Yes. The only other abnormality that was found at autopsy was a very large and active-looking thymus gland. The genital tract—what was left of it—seemed normal.

## HOSPITALS AND THE DOCTOR

Boston is proud of its hospitals and its doctors. They have made this city one of the really great medical centers of the Western Hemisphere.

Fifteen of Boston's hospitals are members of the Community Federation and depend for a large part of their support on the Greater Boston Community Fund. In 1938, Community-Fund hospitals supplied 763,155 days of hospital care to 70,252 patients, half of whom paid nothing or only a fraction of the regular charge. More than a million examinations and treatments were provided by outpatient departments and dispensaries. Visiting nurses from organizations supported by the Community Fund made 277,623 calls to 44,354 patients. This is a splendid record of accomplishment.

But, to quote President Conant, of Harvard University, speaking recently to a group of work-

ers in Greater Boston's 1939 Community Fund Campaign:

The list of things that these institutions could not accomplish because of lack of funds is long and the implication of these deficiencies serious. What the meaning of these deficiencies would indicate in terms of the alleviation of human suffering, no one can predict. It is not enough to recount merely the number of free beds for the care of patients that should be added or the need for increased convalescent care for little children and for enlarged staffs of visiting nurses. It is not only the support of the needs of the local hospitals that is at stake, unless these institutions are in sound financial health they cannot be the centers for the type of fine medical work for which this city has long been famous.

No one will deny the importance of good hospitals to medical education and the advancement of medical knowledge. To quote Dr. Conant again:

The care of the sick, the training of doctors and the advancement of medical knowledge are all aspects of the work of the modern hospital which are intimately associated with each other.

I want to emphasize that after a man has received his medical degree he gets the final and all important part of his training in the hospital, quite apart from any connection with the medical school. Every one of us who has reason to be grateful to a physician or surgeon has reason to be grateful to our hospitals.

Every agency that promotes the improvement of medical care, the bettering of medical education and the advance of medical knowledge should receive the whole-hearted support of all members of the medical profession, even though it necessitates a certain amount of personal sacrifice. Do not fail to contribute to the Community Fund!

## DR. CANNON HONORED BY NATIONAL SOCIETY

THE election of Dr. Walter B. Cannon as president of the American Association for the Advancement of Science is a fitting recognition of a great leader in American science. The list of his published writings—about two hundred and forty titles in all—is long and impressive, so too is the list of honors that have been heaped on him from far and wide. But impressive as are these evidences of achievement, they are wholly inadequate

to portray the warm-hearted human being whose wise guidance has inspired countless disciples and sent them forth equipped to carry on scholarly researches in physiology, and thus bear the torch of his learning to the ends of the earth

Dr Cannon has made his own way in the world. Coming from the Middle West to Harvard, unknown and without friends in the East, he worked his way through college and then, after his graduation from the medical school in 1900, rose rapidly to the front rank of the world's great scientists

His first notable achievement was the ingenious study of the digestive tract by mixing an insoluble radiopaque salt with food and then observing and photographing the resulting shadow obtained by means of the roentgen ray. This expedient served his research at the time, and has served diagnosis ever since, all over the world. In 1911 the results of the investigations thus begun were assembled in a volume entitled *The Mechanical Factors of Digestion*.

During this early stage in his career, only six years after graduation from medical school, he was appointed George Higginson Professor of Physiology, a post he has held for thirty-two years and still holds.

To his penetrating insight significant effects of strong emotion on the digestive functions then revealed an important field of research. The effects of emotional states on physical well-being had been the subject of much loose thinking and lack of thinking, they had been capitalized by faith healers of many cults and had been dismissed with skepticism by physicians of small vision. Dr Cannon placed an important group of phenomena in this hitherto shadowy realm on a scientific foundation. These researches dealt chiefly with the control of endocrine secretions through the sympathetic nervous system. Of these experiments Dr William H. Howell\* said:

It is the information they have brought us in regard to the physiological significance of this diffuse append

age to the central nervous system that I would reckon as Cannon's most important contribution. He conceives of the sympathetic system as not essential for the bare maintenance of life under uniform or protected conditions, but as fulfilling the functions of an emergency mechanism which comes into play under the strain of marked environmental changes, such as exposure to cold, hypoglycemia, asphyxia, muscular effort and, especially, strong emotional excitement. Under these conditions the system is reflexly affected as a whole with the results of an increased secretion of adrenalin, a mobilization of sugar in the circulation, a more rapid heart beat, a change in the distribution of blood, an increase in the circulating red corpuscles and a deeper ventilation of the lungs, all of them reactions that tend to put the animal into a more favorable condition to protect itself from environmental stresses.

Dr Cannon has conveyed the idea of the emergency function of the sympathetic nervous system and of its important effector, the adrenal medulla, with the vivid simile "placing the body on a war footing."

This thesis is developed in the volume *Bodily Changes in Pain, Hunger, Fear and Rage*, published in 1915. The book presents one of the most important concepts of modern science, drawn from a bewildering mass of observations. In this array of physical facts, which to a lesser mind would be unrelated, Dr Cannon, combining the vision of a philosopher with the observation of a scientist, saw a great biological truth.

Professor C. Macfie Campbell, drawing the moral for the medical profession, compared the outworn point of view to a study of the blood chemistry in Dr Cannon's experimental cats by an investigator who was ignorant of the all important emotional stimulus provided by the barking dog. "We study the cat and forget the dog." Dr Cannon long ago recognized that functional stress may lead in time to structural change, the diagnostician who does not know this truth may well mistake effect for cause.

From these studies Dr Cannon was drawn into the maelstrom of war-time medicine. Going overseas in April, 1917, as a first lieutenant in the Medical Corps of the United States Army, he was rapidly promoted to the rank of lieutenant colonel, while his duties correspondingly increased in im-

portance During this period he served with Professor W M Bayliss on the English Committee on Shock, and thus brought his research acumen and experimental skill to bear on a problem in surgery which the casualties of war had raised to one of supreme importance In this assignment Dr Cannon played a major part in establishing the important conclusion that secondary surgical shock is largely due to absorption of toxic material from masses of damaged tissue For this work he was made a Companion of the Bath by the British Government in 1919 and awarded the Distinguished Service Medal by the United States Government in 1922.

After the war Dr Cannon returned to his researches on the sympathetic nervous system and endocrine glands His further work revealed the important substance or substances which he designated "sympathin," whose function as a mediator of smooth-muscle action is a key to much that is new and important in physiology He then introduced another broad concept, "homeostasis" or the property of the organism whereby it compensates for a variety of disturbing influences and thus maintains the "steady states" which must surround the tissues of the body if they are to live and function This concept is set forth in *The Wisdom of the Body*, published in 1932, in which he advances more boldly than in previous works the philosophic implications

And still with tireless zeal his quest for new truth goes on May it go on for many years to come, for every year brings large rewards in knowledge, the quest of which is his chief joy and the fruits of which enrich the world of learning

## SECTION OF OBSTETRICS AND GYNECOLOGY

RAYMOND S. TITUS, M.D., *Secretary*  
330 Dartmouth Street  
Boston

### POSTPARTUM HEMORRHAGE

Mrs M S, a thirty-six-year-old gravida III at term, entered the hospital on October 2, 1938, for elective induction the following day

A series of selected case histories by members of the section will be published weekly  
Comments and questions by subscribers are solicited and will be discussed by members of the section.

Her past history included measles, mumps, chickenpox and diphtheria Her tonsils had been removed Catamenia began at thirteen, were regular with a twenty-eight-day cycle and lasted six days Her last period was December 21, 1937, making her expected date of confinement September 28 In June, 1933, she had had a labor which was terminated by version, the baby weighing over 9 pounds Her past history was otherwise non-contributory, as was the family history

Her present pregnancy had been normal She was first seen on August 25, when she was about thirty-six weeks pregnant Her weight was 146 pounds, which was a gain of 18 pounds beyond her usual weight Her heart was not enlarged, there were no murmurs Her lungs were clear and resonant, there were no rales On September 29, four days before induction, she weighed 144 pounds Her blood pressure was low—104 systolic, 60 diastolic, the urine contained no albumin

On October 3 at 9 a m after castor oil and quinine, the uterus was definitely irritable Vaginal examination showed the cervix to be flat, the external os admitted one finger, and the internal os was entirely obliterated The membranes were ruptured artificially, with the escape of a large amount of fluid One minim of pituitary extract was given At 12.30 p m rectal examination showed that the head was in the pelvis and that the cervix was dilated to the width of one finger, labor had not yet been well established At 3.45 p m rectal examination showed the head low and the cervix three-quarters dilated Six grains of Nembutal had been given at 2 p m, but this had been vomited, 6 gr were then given by rectum A normal ODP delivery was accomplished at 4.26 p m The baby was a male weighing 9 pounds, 13 ounces The placenta followed immediately at 4.30 p m and was intact, with membranes complete There was more than the normal amount of fresh bleeding, but the uterus contracted well after the usual injection of pituitary extract and Ergotrate

An hour later the patient began to bleed, but not an unusual amount Her color was good, her pulse rate was 80 Not long after this she had no radial pulse and no appreciable blood pressure, in spite of which her color was good, she was not sweating, and she was warm Since it did not seem that she had lost enough blood to account for her condition, it was inferred that she was suffering from shock, and she was given an ampule of 50 per cent glucose intravenously This raised her blood pressure to 85 systolic, and her pulse became palpable at the wrist, with a rate of 110 The uterus became flabby, in spite of intravenous pituitary extract By 6.30 p m she was

to portray the warm-hearted human being whose wise guidance has inspired countless disciples and sent them forth equipped to carry on scholarly researches in physiology, and thus bear the torch of his learning to the ends of the earth

Dr Cannon has made his own way in the world. Coming from the Middle West to Harvard, unknown and without friends in the East, he worked his way through college and then, after his graduation from the medical school in 1900, rose rapidly to the front rank of the world's great scientists.

His first notable achievement was the ingenious study of the digestive tract by mixing an insoluble radiopaque salt with food and then observing and photographing the resulting shadow obtained by means of the roentgen ray. ## MAINE NEWS

### GRADUATE FELLOWSHIPS IN OBSTETRICS AND GYNECOLOGY

The Bingham Associates Fund, by offering fellowships, is affording practicing physicians of Maine the opportunity to pursue a course of graduate study in the field of obstetrics and gynecology in Boston. This work will be conducted under the control of the faculty of Tufts College Medical School. The facilities of the New England Medical Center, the Joseph H. Pratt Diagnostic Hospital, the Boston Dispensary and the Evangeline Booth Maternity Hospital will be utilized.

The Evangeline Booth Hospital, with about five hundred deliveries a year, is under the control of the professor of obstetrics of Tufts College Medical School. All the clinical teaching material at this institution will be available for the benefit of these fellows. By observation and actual personal delivery of patients, the most modern methods and the most rigid technic of good hospital obstetric practice will be demonstrated and taught. Much time will be devoted to prenatal clinic examinations and care, and also to ward rounds for instruction in postpartum care.

These fellowships are for one month each and are available to graduates of approved medical schools. Each one-month fellowship carries an honorarium of \$250. Rooms and meals are available for fellows at reduced rates in the Medical Center. Any Maine doctor wishing to secure such a fellowship is requested to write to Samuel Proger, M.D., 25 Bennet Street, Boston, Frederick R. Carter, M.D., 22 Arsenal Street, Portland, Maine or Frederick T. Hill, M.D., Professional Building, Waterville, Maine.

## NOTES

The Maine Board of Registration of Medicine has recently announced that the following physicians have been licensed to practice medicine and surgery in Maine, as of November 9, 1938: Henry S. Hebb, M.D., Bridgton; Thomas B. Hoxie, M.D., Belfast; Theodore J. Hughes, M.D., Portland; Paul A. Jones, M.D., Union; and Joseph P. Seltzer, M.D., Fairfield.

The following physicians have become members of the Maine Medical Association: Androscoggin—James Sansoucy, M.D., Lewiston; Cumberland—Carl Corson, M.D., Robert T. Phillips, M.D., and E. Allen McLean, M.D., Portland; Hancock—James H. Crowe, M.D., Ellsworth.

## CORRESPONDENCE

### REGULATIONS RELATIVE TO TRANSFUSIONS

*To the Editor*—At the last meeting of the Department of Public Health, on Tuesday, January 10, the following Regulations Relative to the Use of Blood or Other Tissues for Purposes of Transfusion, etc. were passed, effective ninety days from date of adoption, that is, on April 10, 1939.

These regulations have been prepared only after consultation with representatives of hospitals, of the Massachusetts Medical Society, of the Massachusetts Hospital Association

and of serologists and syphilologists. Doubtless they will be in conflict, here and there, with present practice, and possibly the conflict will be serious. We trust that if they prove to be unreasonable under certain circumstances, the attention of the Department will be called to the fact in order that they may be so amended as to be reasonable.

The suggestion is offered by the Department that much of the annoyance of blood testing for syphilis may be overcome by the use of rapid or exclusion blood tests, which may be performed within a relatively few minutes just before the transfusion. Such a test, when performed in a laboratory approved by the Department for making such tests, being performed not only within the thirty days first mentioned in the regulations but also within the five days mentioned later in the regulations, will take the place of both.

The State Wassermann Laboratory is prepared to assist in the training of technicians in the performance of rapid tests and to provide the antigen for their performance. Any hospital or institution wishing to have its technician trained or to obtain antigen should communicate with Dr. William A. Hinton at the Wassermann Laboratory, 25 Shattuck Street, Boston.

PAUL J. JAKMAUW, M.D.,  
*Commissioner of Public Health*

State House,  
Boston.

\* \* \*

### REGULATIONS RELATIVE TO THE USE OF BLOOD OR OTHER TISSUES FOR PURPOSES OF TRANSFUSION, ETC.

(Under the provisions of the General Laws,  
Chapter 111, Section 6.)

No person shall introduce the blood or any unsterilized fraction of the blood or tissue of any person, hereinafter called the donor, into the body of another person, by transfusion or otherwise, unless said donor has never had syphilis or malaria and is found to be free from infection with any disease transmissible by such transfusion or introduction of blood or tissue and which has been declared by the Department of Public Health to be dangerous to the public health, so far as such freedom from past and present infection may be determined by the following examinations and tests:

1. A history, carefully taken by a registered physician immediately before the said transfusion or introduction of blood or tissue, as to past or present infection with syphilis or malaria and as to possible exposure to syphilis within the preceding two months and as to signs or symptoms of infection with any disease dangerous to the public health at the time of the examination.

2. A careful physical examination by a registered physician immediately before the said transfusion or introduction of blood or tissue, to consist at least of a careful inspection of the skin from head to feet for any rash or eruption, of the mouth and throat for enanthem, of the genitalia for any lesion or scar, and the temperature.

3. A blood test for syphilis made upon a specimen of the donor's blood, collected not more than thirty days prior to the date of transfusion or introduction of blood or tissue, provided that, in the case of an emergency transfusion, if no previously tested donor is immediately available and a rapid blood test for syphilis cannot be made, the blood test hereinbefore required may be omitted but such omission and the reason

oozing a good deal more than she should have been and looked poorly, there was no clotting. The uterus was packed, and no cervical laceration was found. Because of the hemorrhage it was decided to give a transfusion, but this was not done so quickly as it should have been, due to difficulty in obtaining a suitable donor. The uterus remained flabby. The patient continued to flow, in spite of the pack. It was evident that all the blood going in was coming out, and hysterectomy was decided upon. A second transfusion was given. As soon as another donor was available, a third transfusion was started and the patient prepared for operation. Hysterectomy was performed very quickly. No blood was found in the peritoneal cavity. At the conclusion of the operation some blood did come from the vagina but not more than 100 cc. There was no immediate change in the patient's condition. A fourth transfusion was begun as soon after the operation as another donor could be obtained. Respirations ceased before this transfusion was completed.

An autopsy, performed eleven hours post mortem, showed nothing abnormal except for an increased number of normoblasts in the bone marrow. The uterus measured 7 by 12 by 8 cm. On section the myometrium was 4 cm in thickness, it was soft and pale brown, and numerous dilated sinuses could be made out between the muscle fibers. The uterine cavity was smooth, and there were no hemorrhagic points. The decidua vera was pink and quite thin. There were no obvious cervical lacerations. On section, the muscle bundles were seen to be separated by wide spaces, a few of which contained red blood cells, the capillaries were dilated.

*Comment* There are several interesting points about this case. Her appearance was deceptive. Her condition was not appreciated, and transfusion was not done so soon as it should have been. The blood did not clot. It is perfectly possible that her blood pressure was negligible long enough to have interfered with the functioning of the cerebral tissue. She undoubtedly bled more than was realized, this resulted in shock which was so profound that it caused absolute atony of the uterus, from which she did not rally, even after several transfusions.

There is very little more to add about this catastrophe. The difficulty in getting a compatible donor was unfortunate. A blood bank would have obviated the delay and possibly saved the patient's life.

Born in Roxbury, she received her degree from Tufts College Medical School in 1900. She was a member of the American Medical Association and the Massachusetts Medical Society. A former school physician, she had been associated with the Massachusetts General Hospital, the Children's Hospital and the New England Hospital for Women and Children.

A sister, Dr. Elizabeth T. Gray, and a nephew survive her.

---

**McKALLAGAT**—PETER L. McKALLAGAT, M.D., of Lawrence, died January 20, at Miami, Florida. He was in his fifty-seventh year.

Dr. McKallagat received his degree from Columbia University College of Physicians and Surgeons in 1906. He was a member of the American Medical Association and of the Massachusetts Medical Society.

His widow, a daughter, a son and three sisters survive him.

---

**STAPLES**—CLARENCE H. STAPLES, M.D., of 180 Summer Street, Malden, died January 17. He was in his sixty-second year.

Born in Lunenburg he graduated from the Boston Latin School, from Wesleyan University and, in 1904, from the Harvard Medical School. He was an intern for two years at the Boston City Hospital and opened practice in Malden in 1906.

Dr. Staples founded the Malden Contagious Hospital and was a member of the staff of the Malden Hospital. He was a member of the American Medical Association and the Massachusetts Medical Society.

His widow, a son, Dr. Clarke Staples, two daughters, a brother and two grandchildren survive him.

---

## MISCELLANY

### GEORGE H. BIGELOW MEMORIAL

The George H. Bigelow Memorial Committee has completed its task and turned over to the Boston Medical Library \$1038.30, which has been contributed by Dr. Bigelow's friends.

This money was given for the purpose of providing a permanent fund, the income of which is to be used to purchase books on public health, cancer, medical economics and related subjects. The books are to be selected by a committee composed of the librarian of the Boston Medical Library, the dean of the Harvard School of Public Health and the commissioner of public health. A section in Holmes Hall has been set apart for these books.

As a nucleus for this collection, the Commonwealth Fund of New York has contributed fourteen volumes of their publications and a few writers on public health have donated copies of their books. It is hoped that additional gifts of books or money for the Bigelow Library will be made from time to time and sent to the librarian of the Boston Medical Library.

Two friends of Dr. Bigelow who prefer to be anonymous have presented to the library a bookplate, designed by Miss Mary Sears, to be placed in each book purchased from the fund. Each donor to the fund has received a print of the bookplate. All who have seen it believe that it is an excellent likeness of Dr. Bigelow and that the design as a whole is of unusual merit.

The following were members of the George H. Bigelow Memorial Committee: Henry D. Chadwick, M.D., chair-

## DEATHS

**GRAY**—ALICE M. GRAY, M.D., of 149 Warren Street, Roxbury, died January 18.

Saturday, February 18—Hospital Case Presentation. Dr S J Thannhauser  
 Tuesday, February 21—Allergy Clinic with Case Presentation. Dr E. A. Brown.  
 Thursday, February 23—Medical-Social-Service Case Presentation. District Service and Social-Service staffs.  
 Friday, February 24—The Present Status of Specific Therapy for Pneumonia. Dr Maxwell Finland.  
 Saturday, February 25—Hospital Case Presentation Dr S J Thannhauser  
 Tuesday, February 28—Diabetic Clinic. Dr Joseph Rosenthal

#### ALUMNI DAY, NEW YORK UNIVERSITY COLLEGE OF MEDICINE

Alumni Day of New York University College of Medicine will be held on February 22. Following opening remarks by Dr Edward S Rimer, president of the Alumni Association, and Dr E. D. Friedman, the morning will be devoted to a series of formal lectures on 'Diseases of the Chest, which will be given at the medical school Luncheon at the school will be followed at the Bellevue Hospital by clinic and case demonstrations concerning pulmonary disease. Late in the afternoon Dean Currier McEwen will be host at an informal reception in the Dean's office.

Alumni who expect to attend the meeting are requested to communicate with the secretary of the Alumni Association, Dr Phineas Bernstein, 1100 Park Avenue, New York City

#### CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS, UNDER THE PROVISIONS OF THE SOCIAL SECURITY ACT

CLINIC	DATE	ORTHOPEDIC CONSULTANT
Haverhill	February 1	Arthur T Legg
Lowell	February 3	Albert H. Brewster
Salem	February 6	Harold C Bean
Brockton	February 9	George W Van Gorder
Gardner	February 14	Mark H Rogers
Springfield	February 15	Garry deN Hough, Jr
Worcester	February 17	John W O'Meara
Pittsfield	February 20	Francis A. Slowick
Fall River	February 27	Eugene A McCarthy
Hyannis	February 28	Paul L. Norton

#### MEDICAL CLINIC AT THE PETER BENT BRIGHAM HOSPITAL

At 3.30 p. m. on Thursday, February 2, in the amphitheater of the Peter Bent Brigham Hospital, Dr Henry A. Christian, Hersey Professor of the Theory and Practice of Physic, Harvard Medical School and physician in-chief, Peter Bent Brigham Hospital, will give a medical clinic. Practitioners and medical students are cordially invited to attend.

#### MASSACHUSETTS GENERAL HOSPITAL

A meeting of the Hospital Research Council will be held in the Ether Dome of the Massachusetts General Hospital, on Tuesday, January 31, at 5 00 p. m.

#### PROGRAM

Prostagmin. Dr Henry R. Viets  
 Radioactive Iodine. Dr Saul Hertz  
 Development of Emphysema in Chronic Bronchial Asthma. Dr Tracy B Mallory  
 Studies of Plasma Volume. Dr Edward Hamlin, Jr  
 HENRY K BEECHER, M.D., *Secretary*

#### FAULKNER HOSPITAL CLINICOPATHOLOGICAL CONFERENCE

The monthly clinicopathological conference of the Faulkner Hospital will be held on Thursday, February 2, at 5 00 p. m.

There will be a discussion of cases by Dr Henry C Marble and Dr Theodore L. Badger

#### WORCESTER DISTRICT MEDICAL SOCIETY

The next meeting of the Worcester District Medical Society will be held at the Worcester State Hospital, on Wednesday, February 8

A Swiss motion picture 'The Eternal Mask' will be shown. It is a dramatic and imaginative study of a patient who develops a psychosis.

GEORGE C TULLY, M.D., *Secretary*

#### TRUDEAU SOCIETY

A meeting of the Trudeau Society will be held on February 2 at the Beth Israel Hospital, at 8 15 p. m.

Dr Edgar Mayer, assistant professor of medicine at Columbia University College of Physicians and Surgeons, will speak on 'Diet in the Treatment of Tuberculosis'. Discussion will be opened by Drs Ernest B Emerson and Leon Alley

Physicians and students are cordially invited to attend.

MOSES J STONE, M.D., *Secretary*

#### LAWRENCE CANCER CLINIC

The regular Lawrence Cancer Clinic, to be held at the Lawrence General Hospital, 1 Garden Street, Lawrence, on Tuesday, February 7, at 10 00 a. m., will be a demonstration and teaching clinic for physicians, with Dr Channing C. Simmons, of Boston, associate in surgery in the courses for graduates at Harvard Medical School, surgeon-in-chief to the Collis P. Huntington Memorial Hospital, member of the Cancer Commission of Harvard University, and consulting surgeon to the Massachusetts General Hospital, present as consultant. Physicians of the north half of Essex County are invited to accompany any of their patients whom they desire to have this service or to send them with a note. A report will be returned to every physician who sends a patient. The service is gratis. Any physician is welcome to attend the clinic.

This clinic is endorsed by the Committee on Postgraduate Instruction of the Massachusetts Medical Society

ROY V BAKETEL, M.D.,  
 CHARLES J BURGESS, M.D.,  
 JOHN J MCARDLE, M.D.,  
 HARRY H. NEVERS, M.D.,  
 THOMAS V UNLAC, M.D.,  
 J. FORREST BURNHAM, M.D., *Chairman*

therefor shall be made known to the recipient if possible, or to the recipient's guardian or nearest relative if available, and shall be noted in the record herein-after described.

4 Exception. If an infant under two weeks of age is to be transfused with, or to receive an injection of blood from its own mother, the examination or testing of said mother for syphilis or any other disease dangerous to the public health is not required under these regulations

At the time of transfusion a specimen of the donor's blood and a specimen of the recipient's blood shall be collected for subsequent test for syphilis, provided, that if a blood test for syphilis was made upon the donor's blood within five days before transfusion, said specimen need not be collected, and provided, that if the recipient's blood was tested previously during said recipient's present hospitalization, or present illness if not in a hospital or institution, said specimen of the recipient's blood need not be collected.

Each and every specimen of blood to be tested for syphilis under the provisions of these regulations shall be forwarded, within twenty-four hours after collection, to the laboratory where the test is to be made, said specimen of the donor's blood to be labeled "blood donor—emergency if a prompt report is desired. Each and every blood test for syphilis, made under the provisions of these regulations, shall be made in the Wassermann Laboratory of the Department of Public Health or in a laboratory approved by the Department for performing blood tests for syphilis

The name, age, sex, color, marital status and address of both donor and recipient, the type of blood test performed, the results of the tests and examinations herein required, by whom performed, the date of the transfusion, the name of the physician who performed it, the omission of any blood test herein required and the reason therefor, shall be entered in the permanent records of the hospital, institution, clinic or physician under whose jurisdiction the transfusion was performed, and in such a manner that all of the said data may be readily located by reference to the recipient's medical record.

No blood, drawn for deferred transfusion, herein after called banked blood, shall be used for such transfusion, which has not been drawn under the provisions of these regulations as they apply to the donor of blood for non-emergency transfusions, provided, that the date of collection for banking shall be substituted for the date of transfusion, and provided, that the recipient's medical record shall identify the bank from which blood was used rather than the donor or donors to the bank, and provided, that the name, age, sex, color, marital status and address of the donor, the results of the tests and examinations of the donor herein required, by whom performed, and the date of collection of the donor's blood for banking shall be entered in a permanent record which shall identify the bank to which said donor contributed blood.

Approved and adopted at a meeting of the Department of Public Health held on January 10, 1939 Effective ninety days from date of adoption

## CONTRACEPTIVE ADVICE

To the Editor Since the *New England Journal of Medicine* is the official organ of the Massachusetts Medical Society, it is reasonable to assume that the opinions ex-

pressed in its editorials are not merely the personal opinions of one or more editors but represent the official attitude of the Society as a whole. The statement that the *Journal* does not hold itself responsible for statements made by any contributor certainly does not relieve it of responsibility for statements made in its editorial columns

The editorial of January 5, entitled "The Legal Status of Contraceptive Advice in Massachusetts," offends the consciences of a great many members of the Society

May I ask you for myself personally and out of consideration for the many Catholic members of the Society to make it plain without delay on the editorial page of the *Journal* that the opinion on birth control expressed in the above mentioned editorial does not represent the official stand of the Massachusetts Medical Society?

MARGARET C McMANAMY, M.D

40 Lakewood Street,  
Worcester, Massachusetts

The editorial to which our correspondent refers represents no official stand of the Massachusetts Medical Society. It does express an opinion of the editorial staff concerning the right of physicians to practice their profession according to its rules of ethical conduct and according to their own consciences. It is not intended to offend any member of the Society, nor, we believe, will it do so in the case of those who still believe in the principles of free opinion, free speech and freedom of religious worship on which this country was founded. Ed

## THE PROTEAN CHARACTER OF THE LEUKEMIAS AND OF THE LEUKEMOID STATES\*

HENRY JACKSON, JR., M.D.†

THE classic features of both the acute and the chronic leukemias are well known to all, and lead in the majority of cases to a correct diagnosis and thus to appropriate treatment and accurate prognosis. There are, however, certain deviations from the usual picture which, though uncommon, are of practical importance because of their diagnostic, therapeutic or prognostic implications. Not all patients having the peripheral blood picture of leukemia actually suffer from that disease, not all cases of leukemia present, in the early stages of their disease at least, those features by which we are accustomed confidently to diagnose the condition. It is our present purpose to describe briefly some of these borderline cases.

It is generally agreed that, on the average, the chronic leukemias, whether myelogenous or lymphatic, terminate fatally in about three years from the onset of symptoms.<sup>1</sup> All too frequently, the course is even more rapid. Yet there are, rarely, notable exceptions to this general rule, and these very exceptions should render us cautious in our initial prognosis, particularly when the patient is relatively symptom-free at the time the condition is discovered. Some 10 per cent of patients with chronic leukemia, whether lymphatic or myelogenous, survive more than five and up to ten years.<sup>1</sup> Very rarely they live even longer.

*Case 1* I E., a 69 year-old woman, complained early in 1929 of lassitude, loss of strength and generalized aches and pains. There were no more specific symptoms. On examination she was found to be a frail woman, older than her years would indicate. The lungs were clear, the heart was normal. There was moderate arteriosclerosis. The spleen was felt 2 cm below the costal margin, the liver was just palpable on inspiration. There was slight generalized lymphadenopathy. Otherwise the physical examination was essentially normal. The red-cell count was 4 800 000 and the hemoglobin 85 per cent. The

white-cell count was 59,000, with 99 per cent mature lymphocytes. The platelets were present in normal numbers. By all criteria the patient had chronic lymphatic leukemia and death would have ensued within the next 2 or 3 years, if one were guided by the general averages which apply to this disease. Yet her condition has remained essentially unchanged to the date of writing. From time to time she has been given high voltage x-ray therapy over the splenic area. Her weakness has continued, and indeed increased, her strength has gradually failed, yet in May, 1938, 9 years after onset, the red-cell count was 4,100,000 and the white-cell count was only 16,800, with 72 per cent mature lymphocytes, 20 per cent mature polymorphonuclears and 8 per cent monocytes. Senility seems to be increasing, yet the leukemia remains essentially unaltered, indeed, it can hardly be said to have contributed in any important manner to her present state.

*Case 2* F B M., a 42 year-old man, noticed in 1926 a generalized, painless lymphadenopathy, otherwise he felt perfectly well. Physical examination showed great enlargement of the lymph nodes in the neck, axillas and groins. The nodes were rubbery in consistency, discrete and freely movable. They varied in size but averaged about 4 cm in diameter. The spleen reached nearly to the iliac crest. The liver could not be felt. The white cell count was 186,000, with 93 per cent mature lymphocytes and 7 per cent polymorphonuclear neutrophils. The red-cell count was 4,350,000. The general condition was good and there were no complaints besides the enlarged lymph nodes, which caused him some worry and were naturally disfiguring. From time to time since 1926 he has received x-ray therapy over the splenic area and the enlarged lymph nodes. With each treatment the white cell count has fallen markedly, only to rise once more in a few months to its previous level. The lymph nodes have fluctuated in a similar manner. The spleen has remained consistently large; indeed, it has always been of unusual size for a case of lymphatic leukemia. In May, 1938, 12 years after onset of his illness, the patient still showed marked lymphadenopathy. The white-cell count was 138,000, with 97 per cent mature lymphocytes. The red-cell count was 4,300,000 and the hemoglobin 85 per cent. Blood platelets were present in normal numbers. The spleen still reached to the iliac crest, but the patient was in excellent general condition, and was able to carry on an active and profitable insurance business.

The most protracted case we are aware of was observed by McGavran.<sup>2</sup> We have reviewed the autopsy material from this case and there can be no question as to the correctness of the diag-

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, the Department of Medicine, Harvard Medical School and the Collis P. Huntington Memorial Hospital, Harvard University.

†Assistant professor of medicine, Harvard Medical School, associate physician, Thorndike Memorial Laboratory, Boston City Hospital and Collis P. Huntington Memorial Hospital, Harvard University.

## SOCIETY MEETINGS AND CONFERENCES

## CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, JANUARY 30

## TUESDAY JANUARY 31

- \*9 10 a m Joseph H Pratt Diagnostic Hospital Hemolysins and Hemolytic Anemia Dr William Dameshek
- \*10 a m 12 30 p m Tumor clinic Boston Dispensary
- 5 p m Massachusetts General Hospital Hospital Research Council Ether Dome
- 8 30 p m Norfolk District Medical Society Evans Auditorium of the Massachusetts Memorial Hospitals 78 East Concord Street Boston

## WEDNESDAY FEBRUARY 1

- \*9 10 a m Joseph H Pratt Diagnostic Hospital Hospital case presentation Dr S J Thannhauser
- \*12 m Clinicopathological conference. Children's Hospital amphitheater

## THURSDAY FEBRUARY 2

- 8 30-9 30 a m Exchange visit Surgical and Orthopedic Staffs of the Peter Bent Brigham and Children's hospitals held this week at the Peter Bent Brigham Hospital
- \*9 10 a m Joseph H Pratt Diagnostic Hospital Group Treatment of Psychoneurosis Dr H I Harris
- \*3 30 p m Medical clinic at the Peter Bent Brigham Hospital
- 5 p m Faulkner Hospital clinicopathological conference
- \*8 15 p m Trudeau Society Beth Israel Hospital

## FRIDAY FEBRUARY 3

- \*9 10 a m Joseph H Pratt Diagnostic Hospital Epidemiological Aspects of Tuberculosis Dr A S Pope
- \*10 a m 12 30 p m Tumor clinic Boston Dispensary
- 12 m Clinical meeting of the Children's Medical Service Massachusetts General Hospital Ether Dome

## SATURDAY FEBRUARY 4

- \*9 10 a m Joseph H Pratt Diagnostic Hospital Hospital case presentation Dr S J Thannhauser
- \*10 a m 12 m Staff rounds of the Peter Bent Brigham Hospital Conducted by Dr Henry A Christian

## SUNDAY FEBRUARY 5

- 4 p m Illustrated public health lecture Faulkner Hospital auditorium Diseases of the Heart and Their Management Dr William H Robey
- 4 p m Free public lecture, Harvard Medical School amphitheater of Building D Health and Hygiene During Pregnancy (for women only) Dr Harold M Teel

FEBRUARY 8—Page 173

MARCH 8—Worcester Memorial Hospital

APRIL 12—Worcester Hahnemann Hospital

MAY 10—Worcester Country Club—Annual meeting

With the exception of the annual meeting in May all the meetings begin with a supper at 6 30 p m which is followed at 7 30 p m. by the business and scientific sessions

## BOOK REVIEWS

*Diseases of the Skin A manual for students and practitioners* Robert W MacKenna. Revised and enlarged by Robert M. B MacKenna. Fourth edition. 557 pp Baltimore William Wood & Co, 1937 \$7.00

This book represents the best British practice of today. Stress is laid on the diagnosis and the detailed treatment of the common dermatoses. The more unusual conditions are discussed in small type and quite briefly. The many formulas are of interest because they represent the English experience of the author and his father over many years. The book is well arranged, with an attempt to discuss cutaneous diseases under an etiologic classification so far as possible. The chapters on diseases due to fungi and the animal parasites are especially well handled, but there is little mention of the late evidence of syphilis of the central nervous system and the circulatory system. There are 168 black and white illustrations and 46 colored plates which add much to the excellence of the book.

*Aids to Biochemistry* E. A Cooper and S D Nicholas Second edition 213 pp Baltimore William Wood & Co, 1938 \$1.50

This is a very comprehensive little book, and is presented primarily for the purpose of review study. It is simple and clear, and quite informative. Methods are presented which are quite satisfactory. The book is recommended for general reading and as an aid to laboratory methods.

*Case 5* C P, a 65-year-old woman, complained in early December, 1935, of weakness and easy fatigability. The previous June she had had a short attack of fever of uncertain origin, accompanied by a moderate lymphocytosis and an enlarged and tender lymph node in the left axilla. From this indefinite illness she had recovered rapidly and completely. In December, she complained of weakness and was found to be running a septic type of temperature ranging at night from 99 to 102°F. Her appetite was poor. On one occasion she vomited a little blood. A few days later she passed a small amount of dark blood by rectum. Physical examination was essentially normal except for a moderate degree of loss of weight, some tenderness low in the left flank and a distended abdomen. There was no lymphadenopathy, neither the spleen nor liver was palpable. The lungs were clear and the heart appeared normal. The red-cell count was 4,210,000 and the white-cell count 10,200, with 11 per cent mature polymorphonuclear neutrophils, 22 per cent immature polymorphonuclear neutrophils, 13 per cent metamyelocytes, 10 per cent myelocytes, 36 per cent lymphocytes and 8 per cent monocytes. The platelets were present in normal numbers. It was suspected that the patient had some obscure infection or a carcinoma of the gastrointestinal tract. She gradually failed without developing any specific or localizing symptoms or signs and died December 27. Autopsy revealed the classical picture of aleukemic myelosis—namely a replacement of the normal marrow elements by stem cells and myeloblasts. There was no leukemic infiltration of the liver, spleen or lymph nodes. During life one could not properly have diagnosed leukemia. Yet the patient died of that disease (or at least one closely allied to it) within 4 weeks from the onset of symptoms.

The diagnostic difficulties become still greater when some other specific disease is more or less closely simulated or when the presenting symptom is such that one's attention is distracted from the underlying blood dyscrasia.

*Case 6* C. C., an 8-year-old girl, complained in June, 1932, of migratory joint pains in the ankles, wrists and elbows. She was found to be running a slight, irregular temperature. The involved joints were swollen, tender and very painful on active or passive motion. There was a soft systolic apical murmur. Otherwise the physical examination was normal. A diagnosis of rheumatic fever was made, and under salicylate therapy the patient improved rapidly, she remained apparently well until August of the same year, when there was a recrudescence of the joint pains and marked loss of weight and strength. The red-cell count was 2,300,000, the hemoglobin 50 per cent, and the white-cell count 400, with 2 per cent polymorphonuclear neutrophils and 98 per cent lymphocytes. The platelets were normal in number. Several blood transfusions were given and the red-cell count rose to 5,000,000 and the white-cell count to 7000, with 66 per cent polymorphonuclear neutrophils, 33 per cent lymphocytes and 1 per cent monocytes. The arthritic pains, however, continued unabated and the child failed rapidly. From the end of August occasional myelocytes and stem cells appeared from time to time in the blood smears, and the platelets fell progressively reaching 20,000 per cubic millimeter on October 10. An x-ray taken shortly thereafter showed fine mottling of the cranial bones and of the pelvis. In addition the long bones showed generalized absorption, most marked at the ends, giving the appearance of rotten wood. On the basis of the clinical

picture together with the x-ray findings, the presence of thrombopenia and occasional very immature white cells in the blood smear, a diagnosis of leukemia was made, it was confirmed by bone marrow biopsy. From then on more and more stem cells appeared in the blood stream, and by January 26, 1933, the red-cell count had fallen to 1,500,000. The white-cell count was 700, with 24 per cent mature polymorphonuclear neutrophils, 2 per cent young polymorphonuclear neutrophils, 6 per cent myelocytes, 40 per cent stem cells and 28 per cent lymphocytes. The patient died shortly thereafter. The diagnosis had for several months been very much in doubt and leukemia was not seriously considered until comparatively late in her disease. Yet there can be but little doubt that it was already well advanced when medical care was first sought, and that the initial "arthritic pains" were in reality due to the same leukemic destruction of the bones that became so prominent a feature of the later illness.

"Arthritic pains" are a not uncommon complaint in children with acute leukemia,<sup>3, 4</sup> in adults they are rarely encountered. The x-ray picture is very characteristic, presenting as it does a moth-eaten or mottled appearance, particularly at the ends of the long bones, periosteal elevation is common, and in conjunction with an abnormal blood in which are found myelocytes and stem cells, be they ever so few in number, the diagnosis of leukemia can be made with some confidence.

Occasionally acute leukemia may start with the signs and symptoms of an acute abdominal emergency.

*Case 7* T F, a 4-year-old boy, was awakened early one morning by severe pain in the right lower quadrant. His doctor found marked tenderness and spasm at McBurney's point, a moderate elevation of temperature and a white-cell count of 18,000. A tentative diagnosis of appendicitis was naturally made and operation was deemed necessary. At the hospital the differential white-cell count showed practically 100 per cent stem cells. Nevertheless, the boy was operated on and the appendix was found to be infiltrated by leukemic cells. Immediate convalescence was uneventful and the patient was discharged on the 10th hospital day, but anemia, hepatomegaly and splenomegaly rapidly developed and he died 2 months after the apparent onset of his condition. He had entered the hospital with an entirely justifiable diagnosis of acute appendicitis, with all the prognostic implications of that condition. He left 10 days later doomed to certain death.

*Case 8* R. M., a robust and active man of 51, was seized with extreme pain in the lower abdomen and presented all the signs of complete intestinal obstruction. There was no fever. He was immediately operated on, but no obstruction was found. Both liver and spleen were moderately enlarged. There was no lymphadenopathy. Post-operatively, the red-cell count was 5,200,000, the hemoglobin 102 per cent and the white-cell count 1000, with 100 per cent stem cells. The platelets were greatly reduced. The patient developed a moderate degree of fever and slight jaundice. There was pronounced enlargement of the salivary glands and lymph nodes in the neck. For a few days there was rapid improvement and the white-cell count rose to 21,000, with a practically normal differential count. Equally rapidly, however, the immature cells reappeared, and 6 days after entry stem cells consti-

nosis The patient, F C, a forty-eight-year-old man, was found on routine examination in 1911 to have a white-cell count of 232,000, with 93 per cent mature lymphocytes The red-cell count and hemoglobin were normal He had very mild diabetes, but presented no symptoms suggestive of leukemia It is impossible to say how long his blood condition had already existed before it was discovered No specific therapy was instituted The patient continued to show the characteristic signs and the hematologic picture of lymphatic leukemia, but remained essentially symptom-free until 1926, when he began to lose weight and suffer from intractable diarrhea It was correctly surmised that these symptoms were traceable to his fundamental blood disorder X-ray therapy promptly relieved the diarrhea and greatly improved the general condition At about the same time, however, he began to complain of angina pectoris Gradually his heart condition became worse and he died in 1935 of coronary thrombosis, twenty-four years after his leukemia had been discovered Autopsy revealed the characteristic leukemic infiltration of the liver, spleen, lymph nodes and bone marrow

It may be argued that these patients did not, in actuality, have lymphatic leukemia, that their life span was inconsistent with such a diagnosis Yet it must be admitted that throughout life they showed the signs, symptoms and laboratory findings usually considered diagnostic of that condition, furthermore, in the case just described, post-mortem examination revealed the essential findings of that disease with splenomegaly, hepatomegaly and generalized leukemic infiltration of the bone marrow

From time to time, therefore, one encounters patients who by all known criteria appear to have the disease we call leukemia, but who, for reasons as yet unknown, live in comparative comfort far beyond the usual duration of this condition Such patients are usually relatively symptom-free early in the course of their illness, and not infrequently physical examination reveals few abnormalities Most commonly these cases have lymphatic leukemia, much more rarely myelogenous leukemia So far as our experience goes, monocytic leukemia is never of long duration

Unfortunately we may also err in our prognosis in the opposite direction Leukemic patients apparently in good condition may be struck down suddenly and death may ensue rapidly when but a short time before one would have said, and with some justification, that the immediate outlook was good We do not refer to a rapidly fatal outcome due to other pathologic conditions, but to that directly traceable to the leukemic state

*Case 3* N S, a 30-year-old woman had been known to have myelogenous leukemia for over a year Under x-ray therapy her initial symptoms,—abdominal distress after meals and weakness,—had abated and her white cell count, previously 150,000, had fallen to 12,200 The differential at various times had shown from 20 to 40 per cent myelocytes The red-cell count had fluctuated between 4,500,000 and 5,000,000 The platelets had gradually diminished from normal to approximately 80,000 per cubic millimeter The patient's general condition, however, seemed excellent, and she was able to carry on an active career provided she rested for an hour or so after lunch each day There was no anemia or lymphadenopathy, and the spleen was just palpable on inspiration. One morning she complained of vertigo, extreme weakness and chilliness Physical examination revealed a very apprehensive woman with a pulse of 160, respirations of 40 and a temperature of 105°F The lungs were clear The peripheral blood picture did not differ materially from that which had obtained during the previous months She was slightly disoriented and so dizzy that she was unable even to sit up in bed. She became increasingly incoherent, disoriented and drowsy and died the next morning, presumably from a massive cerebral hemorrhage, possibly of the intraventricular type. There is every reason to believe that the hemorrhage was directly due to the leukemia.

*Case 4* L W, a 49 year-old man, entered the hospital complaining of slight weakness of 1 month's duration and a mass in the abdomen Physical examination revealed a spleen which reached to the level of the umbilicus, and the patient proved to have myelogenous leukemia, with a white-cell count of 27,000 and a differential count of 40 per cent mature polymorphonuclear neutrophils, 16 per cent metamyelocytes and 20 per cent myelocytes The red-cell count was 3,800,000 and the platelets were considerably reduced in number The general condition was good and the prognosis was considered favorable, chiefly on account of the comparatively small percentage of immature white cells in the blood and the paucity of the symptoms On the 3rd day, before receiving any x-ray therapy, the patient passed a large amount of blood by rectum and died a few hours later Autopsy revealed the characteristic findings of myelogenous leukemia and no cause of death other than the massive intestinal hemorrhage, probably dependent on the hemorrhagic diathesis incident to leukemia

In all instances the patient's family should be advised of the fact that sudden death may occur even though the patient seems to be progressing satisfactorily

The acute leukemias frequently present greater diagnostic problems than do the chronic forms The usual picture of weakness, fever, moderately elevated white-cell count, grossly abnormal differential count with many primitive cells of one series or another, progressive anemia and thrombocytopenia may be very incomplete or even entirely lacking early in the disease Any one of these features may fail to appear until comparatively late In short, the blood findings may reflect but poorly the underlying pathologic condition and unless one bears this fact constantly in mind, serious errors are liable to be made

and the red-cell count, which has been steadily falling, rises rapidly to a normal value. The platelets return and the patient appears to have recovered. After a period of one to five months all the signs and symptoms of acute leukemia suddenly reappear, and the patient dies in a comparatively short time.

Patients may present a peripheral blood picture indistinguishable from that of leukemia yet actually suffer from some entirely different disease, and occasionally one which does not run the fatal course of that condition. It is well known that in sepsis there is frequently a marked shift to the left in the white-cell picture. It is not so generally appreciated that the blood may be indistinguishable from that in leukemia.<sup>6</sup> In patients who are recovering from agranulocytosis and in whom considerable sepsis exists, one may find white-cell counts as high as 155,000, with myelocytes as high as 45 per cent. Under these circumstances it is easy to regard the initial illness as an atypical aleukemic leukemia, and to see in the subsequent elevated white-cell count and the grossly abnormal differential count positive evidence for the leukemic state with its inevitably fatal outcome. In 1 case after an acute agranulocytosis the temperature, which had become normal, started to rise again, the white-cell count rose to 33,000 and the differential count showed 42 per cent early myelocytes. Sepsis was suspected, but on account of the white-cell picture the physician in charge of the case insisted that the condition was leukemia. The patient died of a brain abscess secondary to an unrecognized orbital cellulitis, and postmortem examination failed to reveal any signs of leukemia. Aleukemic leukemia may also be simulated.

*Case 11* J G, a 45-year-old man, was admitted to the hospital July 17, 1937. For 1 week he had had symptoms consistent with a diagnosis of pneumonia—pain in the chest, fever, cough and blood streaked sputum. No blood examination had been made.

Physical examination on entry revealed a semicomatose man with a slight jaundice. There were indefinite signs of pneumonia at the right base. The liver was felt 4 cm below the costal margin. The spleen was easily palpable. The temperature was 104.4°F, the pulse 130 and respirations 28. The red-cell count was 4,000,000, the hemoglobin 75 per cent and the white-cell count 1000, with 23 per cent polymorphonuclear neutrophils, 19 per cent metamyelocytes, 33 per cent myelocytes, 14 per cent stem cells and 11 per cent lymphocytes. The platelets were markedly diminished. A diagnosis of myelogenous leukemia with complicating pneumonia was made. The patient died within 24 hours. Postmortem examination showed lobar pneumonia of the right lower lobe, alcoholic cirrhosis and a hyperplastic bone marrow. There was no evidence of leukemia.

These diagnostic difficulties are materially increased when one remembers that patients who

have had undoubted leukemia, as proved by blood studies and bone-marrow biopsy, may die shortly thereafter and at autopsy show not the slightest evidence of the disease.

*Case 12* J T H., a 68-year-old man, was admitted to the hospital on October 14, 1929, with the chief complaint of a mass in the left upper quadrant. In addition he had some pain in the region of the mass. Physical examination revealed the spleen descending to the level of the umbilicus and the liver could be felt 8 cm. below the ribs. Otherwise the examination was essentially normal. The red-cell count was 3,370,000, the hemoglobin was 68 per cent and the white-cell count was 275,000, with 50 per cent polymorphonuclear neutrophils, 42 per cent neutrophilic myelocytes, 3 per cent eosinophilic myelocytes and 5 per cent stem cells. The basal metabolic rate was +46 per cent. The patient was given x-ray therapy with a moderate drop in the white-cell count and a definite though not marked diminution in the size of the spleen. He gradually failed. One month after admission the red-cell count had fallen to 2,700,000, the hemoglobin to 50 per cent and the white-cell count to 5250. The differential had become essentially normal and the basal metabolic rate had dropped to +4 per cent. The patient died January 26, 1930. Postmortem examination failed to show any infiltration of the liver or spleen. In most places the vertebral bone marrow was completely fatty, and here and there could be seen small areas characteristic (in so far as the particular field was concerned) of leukemia. For the rest, all evidence of the disease had disappeared.

In this case there was no bone-marrow biopsy at entrance to prove the condition, but the elevated metabolism and the occasional leukemic patches in the marrow virtually prove that the patient did in fact have leukemia, and that that disease had given way to aplastic anemia. Mallory<sup>8</sup> reports an almost identical case in which a bone-marrow biopsy confirmed the leukemic infiltration occurring early in the course of the disease.

Many other pathologic states may give rise to blood pictures indistinguishable from that of leukemia.<sup>6</sup> We draw special attention to two, namely miliary tuberculosis and carcinoma.

*Case 13* F K, a 19-year-old man, entered the hospital with a history of weakness and fatigue for 2 months. The temperature was 104°F, the pulse 120, and the respirations 25. Physical examination showed very marked pallor of the mucous membranes and bean sized lymph nodes in each side of the neck, each axilla and each groin. The spleen was easily palpable on deep inspiration. The red-cell count was 2,130,000, the hemoglobin 49 per cent and the white-cell count 6100, with 44 per cent polymorphonuclear neutrophils, 25 per cent myelocytes, 22 per cent myeloblasts, 8 per cent lymphocytes and 1 per cent monocytes. The platelet count was 187,000. The patient continued to run a septic temperature with occasional chills. Blood cultures were repeatedly negative. During the next 2 months he sustained numerous superficial skin abscesses and was regarded as having a subacute myelogenous leukemia with sepsis. The red-cell count fell to 1,900,000, the white-cell count to 2100, with 33 per cent myeloblasts and the platelet count to 46,000. The physical examination remained essentially as on admission. The patient died

tuted 87 per cent of the total white cells. At that time the spleen reached to the umbilicus. The patient died 8 days after his operation. Postmortem examination showed the characteristic findings of acute myelogenous leukemia with infiltration of the liver, spleen, kidneys, intestinal wall and bone marrow.

In the vast majority of instances, once the diagnosis of acute leukemia is established the patient grows steadily worse and responds but little to any therapeutic measure. Occasionally the condition progresses by a series of minor remissions and relapses without there being at any time any question of the correctness of the original diagnosis. In rare cases there occur frank remissions of considerable duration, during which few if any features of leukemia are present and in which the patient returns to apparently excellent health, and unless this fact be borne in mind, serious errors may be made.<sup>5</sup> The original diagnosis may be doubted or even discarded and both the doctor and the family may be lulled into a false sense of security which is in no way justified by the subsequent course.

**Case 9** J. R., a 35-year-old butcher, entered the hospital November 9, 1929. A week before entry he had become very weak and had profuse bleeding from the gums. Fever was noted from the onset. The day before entry a small quantity of fresh blood was passed by rectum. Physical examination showed a pale, prostrated man with greatly swollen and bleeding gums. There were many bean-sized lymph nodes in each side of the neck. The spleen reached to the level of the umbilicus. In the lower rectum could be felt an exquisitely tender mass which bled freely on gentle palpation. The temperature was 100°F. On the day of admission, his red-cell count was 3,120,000 and the hemoglobin 70 per cent. The white-cell count was 11,000, with 90 per cent stem cells, 4 per cent polymorphonuclear neutrophils and 6 per cent lymphocytes. No platelets were seen in the smear. Two days later petechiae appeared in profusion over the neck, shoulders and chest. The temperature rose to 105°F and the patient seemed moribund. The white-cell count fell to 2800, with the differential count essentially unchanged. Within the next few days, however, the count rose precipitately and the differential white count steadily approached normal, the stem cells being gradually replaced first by myelocytes, then by metamyelocytes and finally by mature polymorphonuclear neutrophils. The platelets increased rapidly. The patient gained in strength, the temperature fell to normal, the bleeding ceased, the spleen receded to normal size and the enlargement of the cervical lymph nodes completely disappeared. By December 18, 1 month after entry, the white-cell picture was entirely normal, blood platelets were present in the usual number and the general condition was excellent. The red cell count gradually rose to 5,000,000. During January, February, March and April, the patient was perfectly well in all respects. The physical examination was normal and no abnormalities could be detected in his peripheral blood. No trace of the fulminating disease from which he had suffered in November remained. Suddenly in late April, he was seized with a severe headache. Once more he was found to have the characteristic blood picture of acute leukemia (only 3 days previously the blood smear had been entirely normal) and he died May 5, 5½ months from

onset, after a complete remission of nearly 5 months. A bone marrow biopsy shortly before death revealed the characteristic histologic picture of acute myelogenous leukemia.

What caused the remission? What relation had the first illness to the second? Was the patient temporarily cured of his leukemia, or was it merely that the outward and visible signs of the disease were no longer manifest? These questions cannot at present be answered. But we do know that such remissions occur, and it is obvious that their appearance may cause great confusion, particularly if in the first attack there has been any doubt regarding the diagnosis, we have already seen that in the initial stages of acute leukemia the signs and symptoms may be far from pathognomonic.

**Case 10** N. B., a 5 year-old girl, became ill in November, 1932. She ran a septic temperature reaching to 102°F and became rapidly weaker. The red-cell count on admission to the hospital was 2,000,000. The hemoglobin was 36 per cent and the white-cell count was 13,000, with 9 per cent polymorphonuclear neutrophils, 86 per cent lymphocytes and 5 per cent myelocytes. After 1 month she contracted measles and developed bilateral otitis media and necrosis of the lower lip. The white-cell count fell to 1000 and the differential white-blood count showed 91 per cent immature lymphocytes. The platelet count dropped to 10,000 and the red-cell count fell to 1,200,000. After several blood transfusions and intensive Pentonucleotide therapy the white-cell count rose to 10,200 with a normal differential count, and the red-cell count rose to 4,200,000 early in January, 6 weeks after the initial symptoms. In the meantime the temperature fell to normal, the otitis cleared up and the patient's strength completely returned. She remained entirely well both from a clinical and hematological point of view until May 16, 1933, when she developed bilateral mastoiditis, with a temperature of 105°F. In addition she had generalized joint pains, and x-ray studies revealed the characteristic picture of leukemic infiltration of the bones, just as in Case 6. The red-cell count was 1,800,000 and the white-cell count 23,000, with 97 per cent immature lymphocytes. During the next 6 weeks the patient failed rapidly, and she died in mid July, 8 months after her first illness and 10 weeks after the termination of the 5 month remission. Postmortem examination showed the characteristic features of acute lymphatic leukemia.

Here again we have an example of a dramatic remission after an illness which had all the hallmarks of acute leukemia. As has been said, we are ignorant of the cause of these remissions, but it is important to recognize that they may occasionally occur. In our experience, they usually follow a definite pattern. After a stormy onset, the elevated white-cell count falls rapidly to well below normal, then as rapidly rises once more. The immature white blood cells, initially present in large numbers, become less and less. With the rising white-cell count the differential count becomes steadily more normal. During this time the patient's general condition improves rapidly.

opsy showed that in this region at least the normal elements had been completely replaced by fibrous tissue.

During the ensuing months the red-cell count gradually fell to normal, and it remained at that level from September, 1933, to June, 1938. The hemoglobin dropped gradually from 110 per cent on December 9, 1931, to 52 per cent in June, 1938. The white-cell count fluctuated between 9000 and 28,000, and at all times the differential count showed a definite and increasing percentage of immature cells of the granulocyte series. During 1931 and 1932 the polymorphonuclear neutrophils had varied from 69 to 89 per cent and the myelocytes from 1 to 10 per cent. Basophils were constantly present, and varied between 2 and 5 per cent. By 1934 there were almost constantly present more than 12 per cent myelocytes, and a few nucleated red-blood cells were seen from time to time.

Early in 1938, when the red-cell count had dropped to 3,460,000 and the hemoglobin to 49 per cent, the white-cell count was 18,750 and the differential count showed 42 per cent polymorphonuclear neutrophils, 25 per cent myelocytes, 5 per cent stem cells, 10 per cent basophils and 18 per cent lymphocytes. Seventeen nucleated red cells were seen while counting 100 white cells. The platelet count was 180,000. The blood picture was essentially that of an early myelogenous leukemia. At this time the patient was definitely weaker than ever before. She had lost much weight, the liver reached nearly to the umbilicus and the spleen nearly to the iliac crest.

The basal metabolic rate was +20 per cent, a rate entirely consistent with the degree of myeloid metaplasia which the patient was assumed to have, but rather lower than that

which would probably have obtained in chronic leukemia of this duration and activity.

A second bone marrow puncture was done, and again it showed merely fibrosis of the marrow. In view of the long, relatively asymptomatic course, the initial polycythemia and the bone marrow findings, one must conclude that the condition was one of myeloid metaplasia rather than myelogenous leukemia, as was originally suspected.

#### CONCLUSION

It is apparent from a consideration of these cases that the course of the various leukemias may deviate sharply from the classic one, on the other hand, various other pathologic conditions—some of them curable—may give rise to a blood picture indistinguishable from that seen in this disease.

## HYPERHIDROSIS OF NERVOUS ORIGIN AND ITS TREATMENT BY SYMPATHECTOMY\*

JAMES C. WHITE, M.D.†

BOSTON

**L**IST and Peet,<sup>1</sup> in their excellent articles on the activity of the sweat glands, have shown that these structures respond both to thermal and to psychic stimuli. While heat sweating is a generalized process and is rarely a cause for complaint, hyperhidrosis of nervous origin may become extremely annoying and even incapacitating. The latter variety is usually limited to the palmar and plantar surfaces and to the fingers and toes. Above the wrists and ankles perspiration is normal (Fig. 1). The clamminess of hands and feet may be really disabling. Beads of perspiration may form on the fingertips and wet everything the patient handles. Shaking hands may become most embarrassing, as one of my patients, a lawyer, complained "The law is a handshaking profession and I can't do it!" Another patient, a medical student, could not assist at operations

because the sweat ran over the tops of his rubber gloves. The feet commonly perspire to a similar extent, so that the lower part of the sock or stocking is dripping wet. The feet of one of Telford's<sup>2</sup> patients sweat so excessively that he was forced to take off his boots and empty them of water several times a day. Excellent photographs of the excessive degree of sweating which may be seen in this condition are to be found in an article by Adson, Craig, and Brown.<sup>3</sup>

This type of hyperhidrosis is usually accompanied by some degree of vasospasm, so that the sweaty extremities are frequently cold and at times cyanotic. As patients with Raynaud's disease often have extremely moist, as well as cold, extremities, the two conditions seem to shade imperceptibly one into the other. Unlike Raynaud's disease, hyperhidrosis is frequently seen in men, but both diseases are likely to occur in young and emotionally unstable individuals. Dickens<sup>4</sup> must have been acquainted with such a case to have written his classic description of Uriah Heep. "It

5 months from the onset of his illness, and postmortem examination showed widespread miliary tuberculosis of the lungs, pleura, lymph nodes, spleen, liver and bone marrow. There was no evidence of leukemia.

In certain cases carcinoma may give rise to a blood picture closely simulating leukemia—and this without necrosis, infection or fever.

*Case 14* M. M., a 70-year-old woman, was admitted to the hospital with a story of cough and increasing weakness for 4 months. In addition she had been losing weight rapidly. Her past history was essentially normal except that for 10 years she said she had "glands" in her neck.

Physical examination showed a frail, elderly woman. The thyroid was definitely enlarged, nodular and firm. The liver was palpable 4 cm. below the costal margin. Otherwise there were no notable abnormalities. The temperature was normal, the respirations were 30 to 35 and the pulse was 110 to 130. On entrance the red-cell count was 4,300,000, the hemoglobin 85 per cent and the white-cell count 76,000, with 85 per cent polymorphonuclear neutrophils, 12 per cent myelocytes, 2 per cent lymphocytes and 1 per cent monocytes. The platelets were diminished in number. During the next few days, the white-cell count rose to 180,000, with increasing numbers of early myelocytes, and the patient died on the 4th day. At no time did her temperature rise above normal. Postmortem examination showed slight bronchopneumonia, colloid adenoma of the thyroid and a large mediastinal carcinoma with metastases to the liver and spleen. The bone marrow showed increased activity in both red-cell and white-cell series but no leukemic infiltration.

The following case was still more striking.

*Case 15\** I. R., a 45-year-old carpenter, developed a cough and pain in the chest 6 weeks before admission to the hospital. Physical examination on entrance was essentially normal except for slight dullness at the right apex of the lung, associated with increased tactile fremitus and slight dullness in the right lower axilla. The red-cell count was 4,300,000, the hemoglobin 80 per cent and the white-cell count 51,250, with 85 per cent polymorphonuclear neutrophils, 11 per cent lymphocytes, 2 per cent monocytes, 1 per cent eosinophils and 1 per cent basophils. The patient's temperature fluctuated between 98 and 100°F. Two weeks later the patient experienced a sudden, sharp, severe pain in the left axillary region and immediately coughed up a large amount of foul, blood tinged sputum. Although the red-cell count remained normal the white-cell count rose to 116,000, with 93 per cent polymorphonuclear neutrophils, many of which were band forms. A lateral chest film showed an oval area of consolidation in the central part of the right lung field. The cough, sputum and fever continued and the patient gradually failed and died 2 months after his initial symptoms. Postmortem examination showed a carcinoma of the right lung with metastases to the regional lymph nodes, liver, pancreas, adrenals and kidney. The bone marrow was so hyperplastic as to resemble superficially that seen in leukemia. But the percentage of immature granulocytes in the marrow was no greater than normal, the hyperplasia was patchy rather than diffuse and there was no leukemic infiltration in the liver, spleen or lymph nodes.

The method by which such gross hyperplasia is produced in the presence of carcinoma (especially

of the lung and of the liver, it would seem) is uncertain, but the fact remains that malignant disease may produce a leukemoid blood picture and, as in the case just cited, may result in a degree of bone-marrow hyperplasia superficially resembling that seen in leukemia.

Finally, we wish to refer to that pathologic state which for lack of a better term is now called myeloid metaplasia, a condition which closely simulates leukemia both from a clinical and a hematological point of view, but which runs a more benign course. Its etiology and indeed its pathogenesis is obscure. It would seem probable, however, that for a variety of reasons—abnormal blood supply to the bone marrow, fibrosis of the marrow, osteosclerosis or the like—the normally active and efficient hematopoietic tissues are no longer able to carry on their allotted function and the normally fatty marrow of the femur and tibia, together with the potentially hematopoietic organs such as the liver and spleen, must perforce take over the task of producing the blood cells so necessary for the bodily economy. That these newly called upon tissues are but poor successors to the "red marrow" is attested by the peripheral blood picture, which is, as has been said, leukemoid in type.

*Case 16* L. J., a 51 year-old married woman, entered the hospital on September 28, 1931. Twenty-five years previously she had had a severe attack of jaundice with headache, nausea, vomiting and vertigo. Since that time she had had three similar attacks, the last one in 1923. In 1926 an abscessed tooth was removed and there followed profuse bleeding for 24 hours. A few weeks after this episode there was a massive hemorrhage from the mouth and much blood was found in the stools. An abdominal exploration was performed and a gastric ulcer was said to have been found, although the evidence on this point is not entirely clear. In 1929, the patient's tongue became sore and she lost considerable weight. During the next few years she felt below par, her appetite was poor and she continued to lose weight. Physical examination on entry showed an atrophic tongue, slight pallor of the mucous membrane and a spleen extending 4 cm. below the ribs. Otherwise there were no noteworthy abnormalities. There was no free hydrochloric acid in the stomach, even after histamine. The red-cell count was 5,390,000, the hemoglobin 57 per cent and the white-cell count 28,500, with 70 per cent polymorphonuclear neutrophils, 9 per cent myelocytes, 11 per cent lymphocytes, 3 per cent monocytes, 4 per cent eosinophils and 3 per cent basophils. The platelets were not only unusually large but greatly increased in number. The reticulocytes were 2.8 per cent, the icteric index 70 and the fragility of the red cells normal. A tentative diagnosis of early myelogenous leukemia was made and the patient was given iron by mouth. Within 1 month the red-cell count had risen to 7,000,000 and the hemoglobin to 68 per cent. The patient felt well, but several ecchymoses appeared on each thigh. During the next 6 months the condition remained essentially unaltered and the red-cell count at 7,000,000 or slightly above. In March, 1933, a sternal bone marrow bi-

\*I am indebted to Dr. Tracy B. Mallory of the Massachusetts General Hospital for permission to cite this case.

of the operations reported below make it extremely unlikely that any originate above the second thoracic nerve in man. After reaching the paravertebral sympathetic trunk, all these preganglionic axones run upward to the lowest cervical and upper two thoracic ganglia, where they establish synapses with postganglionic neurone cells whose axones are distributed to the cords of the brachial plexus over the gray rami communicantes (Fig 2)

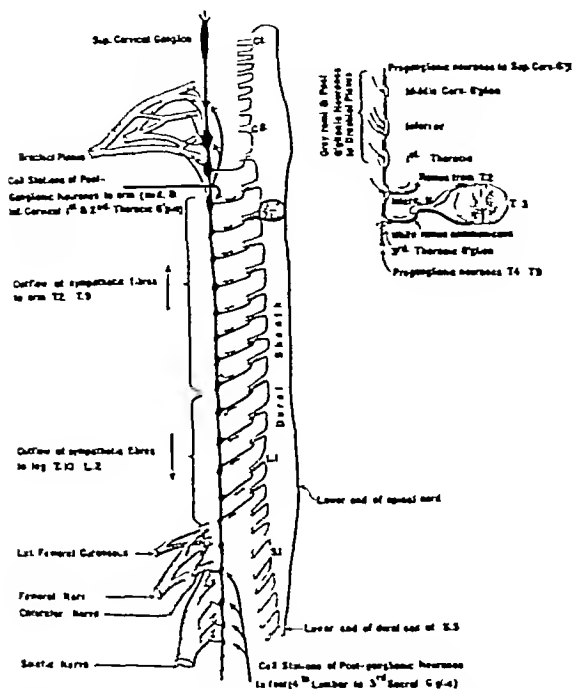

Figure 2 *The Anatomic Arrangement of the Sympathetic Fibers to the Arm and Leg*

The nerve supply to the sweat glands of the foot leaves the cord over the lowest thoracic and upper two lumbar nerves, and is distributed to the roots of the sciatic nerve from the fourth lumbar to third sacral ganglion.

Neurosurgical relief of extreme hyperhidrosis of the extremities has been called to the attention of the medical profession through the reports of Braeucker,<sup>10</sup> Pieri,<sup>15</sup> Leriche and Frierh<sup>16</sup> and Roberts,<sup>1</sup> and the more recent article by Adson, Craig and Brown<sup>4</sup> in this country. In the Massachusetts General Hospital the operation was first performed in 1932.<sup>15</sup> Standardized procedures are now available to sever the sympathetic fibers running to the upper and lower extremities. As the vasomotor and pilomotor fibers are mixed with the sudomotor ones, the operation diminishes vasoconstrictor tone, in addition to causing a total paralysis of sweating and of pilomotor activity. In the case of the lower extremities, resection of the second and third lumbar ganglia can be count-

ed on to stop all sweating below the knees, as well as to produce a lasting vasodilatation. In the case of the arm the sympathetic pathway may be interrupted in its postganglionic portion by cervicothoracic ganglionectomy as proposed by Adson.<sup>19</sup> This results in a Horner's sign (drooping of the upper lid, pupillary constriction and enophthalmos), which is somewhat disfiguring, particularly when the operation is done on only one side. Recent investigation<sup>18, 20</sup> has shown that degeneration of the sympathetic fibers leaves some residual vasoconstrictor tone from the direct action of adrenaline and sympathin on the arterial walls, which become hypersensitive to these chemical mediators after the nerve fibers have degenerated. It is a well-known physiological fact that this chemical sensitization is more accentuated if the peripheral sympathetic pathway is interrupted in its postganglionic rather than in its preganglionic portion. This action of the sympathomimetic hormones does not affect the sweat glands in any way, as they respond only to the chemical action of acetylcholine,<sup>21</sup> but it is of considerable importance to avoid its action on the vascular tree in persons who already exhibit a tendency to abnormal vasoconstrictor activity. A method of denervation which does not produce a Horner's syndrome and causes only a minimal sensitization of the smooth muscle of the vascular walls has been developed by Smithwick<sup>22</sup> and by Telford.<sup>23</sup> In order to interrupt only preganglionic axones to the upper extremity, the inferior cervical and first and second thoracic ganglia are spared, but the sympathetic chain is cut at the level of its third ganglion and all higher connections with the second and third thoracic roots are severed. The details of these operative methods are beyond the scope of this article, but as success depends on a most exact technic, each step outlined in the original description must be followed with care.

It will be noted in the case histories below that hyperhidrosis in the hands was relieved in 1 case by paravertebral infiltration of alcohol around the first and second thoracic ganglia, with only a single night's hospitalization and without any interruption of the patient's employment. A second equally successful result has been obtained by Freeman.<sup>24</sup> Nevertheless it is my belief that with rare exceptions surgical denervation is the better procedure, as its action is certain and the operative risk is almost nil in this group of young and otherwise healthy individuals. After alcohol block there is considerable risk of incomplete results and some risk of producing a troublesome intercostal neuritis.

Certain precautions should be observed in performing these operations. As stated above, a dis-

was no fancy of mine about his hands, I observed, for he frequently ground the palms against each other as if to squeeze them dry and warm, besides often wiping them, in a stealthy way, on his pocket handkerchief"

#### ETIOLOGY

No specific etiologic factor is known for this form of hyperhidrosis, but it is brought about by

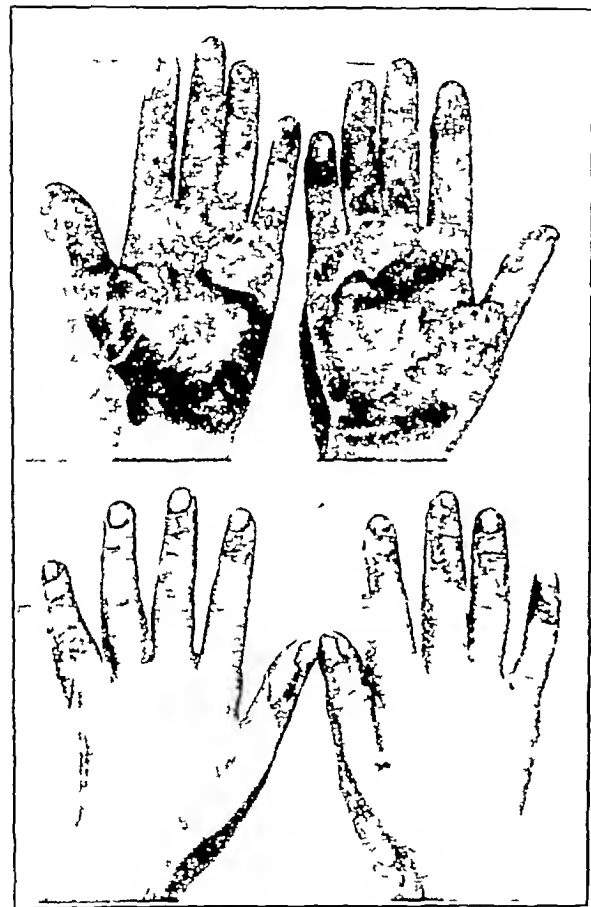

Figure 1 Photographs of the Hands of a Patient (Case 1) with Hyperhidrosis of Nervous Origin

They illustrate the characteristic areas of sweating. Sweat secretion is brought out in black by Minor's starch-iodine method

hyperactivity of the sympathetic nervous system and is exaggerated by nervousness. Just as generalized sweating is frequently seen in high-strung thoroughbred horses in the paddock before a race, in human beings the more localized variety of nervous sweating can be brought out by any difficult mental problem or embarrassing situation. When the normal individual is terrified and breaks out in "a cold sweat," it is the hands and feet that are usually involved. As a result of recent investigations on the role of the premotor

cortex and the autonomic centers in the hypothalamus, it is now known that all forms of visceral activity may be influenced by the psychic state of the individual.<sup>6</sup> Cobb,<sup>7</sup> who is making a psychiatric examination of patients with abnormal vasomotor and sudomotor activity, has reached the conclusion that these individuals have a special psychological make-up which, as he puts it, "is characterized by inner emotional turmoil thoroughly covered and repressed beneath a pleasant but formal appearance and superficially co-operative behavior." It is therefore not a far-fetched hypothesis to assume that the cause of these conditions will be found to lie in the corticodiencephalic mechanisms which control our emotional status.

#### TREATMENT

In the treatment of severe hyperhidrosis medical measures have been unsatisfactory. Application of antisudorific preparations, such as 5 per cent formalin, bring about some local reduction in sweating, but at the expense of maceration and irritation of the skin. Radiation of the skin may cause some atrophy of the glands, but it must be pushed to the point of risking a chronic dermatitis. As spontaneous activity of the sweat glands is mediated by the sympathetic nerves, it ceases entirely when these pathways are interrupted. Charts showing the areas of anhidrosis after various operations on the sympathetic nervous system have been published by Roth.<sup>8</sup>

Sympathectomy was first carried out to reduce hyperhidrosis by Kotzareff<sup>9</sup> in 1919. In this operation the resection included only the cervical ganglia, but the excessive sweating appears to have stopped. The anatomical and surgical aspects of this condition were thoroughly explored by Braeucker<sup>10</sup> and by Hesse.<sup>11</sup> The former stated that the sympathetic sudomotor axones to the hand run over the rami communicantes of the two lowest cervical and the first thoracic ganglia. Hesse<sup>11</sup> and his colleague Juzelevskij, however, found that some additional lower fibers leave the second thoracic ganglion, and this has been confirmed by Kuntz.<sup>12</sup> According to Langley<sup>13</sup> and Braeucker,<sup>10</sup> these fibers leave the spinal cord in the motor roots from the fourth to the ninth thoracic segments. Recent observations of Kuntz, Alexander and Furcolo<sup>14</sup> demonstrate that there are higher fibers which emerge over the second and third intercostal nerves, and that a few fibers to the sweat glands in the cat's paw run in the first thoracic root. Clinical experience has shown that sudomotor axones leave the cord as high as in the second and third thoracic roots, but the results

*Case 3* L L, aged 23 This patient, also a medical student, had noticed excessive sweating of the hands and feet for 13 years This had recently increased to an incapacitating degree. Treatment with formalin and x ray had been ineffective. Otherwise he had always been in excellent health He showed marked sweating of the hands, with a sharp line of demarkation at the wrists Beads of moisture stood out on his palms and the soles of his feet and frequently dropped off. The extremities were cold as well as wet to the touch. The patient admitted that he had been 'nervous' as long as he could remember.

On August 21, 1936, a right preganglionic sympathectomy was performed. Sweating tests performed on discharge showed no trace of perspiration above the second rib on the right side. The patient returned to medical school 1 month later and had no further trouble with perspiration in his right hand (Fig 4) Nine months later

Figure 4 Photograph of the Hands of a Patient (Case 3) Nine Months after Right Thoracic Sympathectomy

*The right palm remains completely dry, the left is dripping wet*

he returned for operation on the left side. After each operation he made a smooth and uneventful convalescence.

A follow up letter 3 months after the second operation stated that the left hand had remained completely dry and warm. The right hand showed a trace of perspiration along the medial side of the palm. This was too slight to be of any concern, and the remaining area of the right arm, and all the left arm, as well as the head and neck, remained completely dry. The patient was in excellent condition and felt better both mentally and physically.

*Case 4* C J, aged 29 The patient, who did secretarial work, stated that his palms and soles had been cold and clammy for 15 years. At times of nervous strain they actually dripped sweat, so that the condition became a social as well as an economic handicap. No other part of his body sweat to an abnormal degree.

On September 10, 1936, a right preganglionic sympathectomy was performed. One week later, the patient after being heated in a chamber at 130°F broke out in a generalized perspiration. The right hand showed no moisture and the right side of his face, neck and upper chest remained strikingly dry, in contrast to the left side, which was covered with large beads of perspiration. On September 19, 1936, a similar operation was performed on the left side.

Three months after the second operation the patient reported that he was back at work and was cured. Six

months later he was seen in New York by a physician, who reported that the hands remained dry, warm and pink.

*Case 5* J R., aged 32 This patient, who had just finished medical school, was about to start on a surgical internship. He was a well-built, athletic individual, but with dripping wet palms and fingers, which made surgical work nearly impossible. In addition to hyperhidrosis he showed a moderate degree of increased vasoconstrictor tone in the extremities. A physical examination showed no other abnormality.

On June 7, 1937, a right preganglionic sympathectomy was done. The patient showed a transitory tendency to perspire in the denervated area about the 4th day after operation. We have observed this on a number of occasions after preganglionic sympathectomy, and have ascribed it to a transitory stimulation of the degenerating preganglionic fibers. It has never lasted over 1 day.

Six months later the patient wrote in answer to a questionnaire that his hand remained practically free from moisture. He had noticed no disagreeable sequelae, and the hand had remained pleasantly warm all the time. He was delighted with the results of the operation.

*Case 6* A McD, aged 36 This patient, a lawyer, well-built but somewhat apprehensive, had noticed excessive sweating of his hands and feet for many years. At first he minded it most in his feet, as his socks were always dripping wet, but at the time of entry his hands were even worse and bothered him extremely in his courtroom work. As I observed him he was constantly wiping his hands with his handkerchief. Except in extremely hot weather, sweating was confined entirely to the characteristic areas. The skin over the hands and feet was corrugated as though the extremities had been soaked in hot water. There had been no visible vasospasm. The general condition was good, and the patient had always been in excellent health. He had tried formalin soaks and found that these helped somewhat with his feet, but very little with his hands. His basal metabolic rate was within normal limits.

On August 31, 1937, a right preganglionic sympathectomy was performed. Since that time his right hand has remained completely dry. Nine months later he returned requesting operation to relieve the extreme sweating of his feet. In spite of frequent formalin soaks he had not been able to reduce the sweating to the point where it would not soak through his shoes. The skin over the palmar areas and toes was severely macerated. On June 2, 1938, a resection of the right lumbar sympathetic chain with the second and third ganglia was done by Dr. Reginald H. Smithwick. On June 9, 1938, a left lumbar sympathectomy was performed. The patient made a very smooth convalescence from both operations and was ready to go home 18 days after the first operation.

In a follow up examination, September 12, 1938, no signs of moisture could be detected in either foot or in the right hand. The patient was most grateful.

#### SUMMARY AND CONCLUSIONS

Excessive sweating of the palmar surfaces and fingers and of the soles and toes is a not uncommon condition in nervous young people. The wetness may become so extreme as to be incapacitating, especially in certain vocations which require skilled work with the hands.

figuring Horner's syndrome can be avoided by leaving intact the palpebral and ocular fibers which pass through the first thoracic root, the first thoracic and inferior cervical sympathetic ganglia. When lumbar sympathectomy is performed on a male patient it is essential not to injure the chain above the second lumbar ganglion. If the fibers which run from the upper lumbar chain to the hypogastric plexus are destroyed, loss of the power of ejaculation and sterility will result. Although a sympathetic denervation of the right hand alone may at times suffice, the procedure must usually be carried out bilaterally. Under these circumstances it is safest to do the operation in two stages. The second operation can be done four days to a week after the first, so that the total period of hospitalization is generally under a fortnight when both arms are denervated, and less than three weeks if both lumbar chains are resected.

#### CASE REPORTS

*Case 1* R. T., aged 25. This woman was a stenographer. She had always had excessive perspiration of the palms of her hands and the soles of her feet, which were continually dripping wet. This was so pronounced that drops of perspiration fell from her fingers and made it extremely difficult for her to work as a secretary. This condition became worse when she was excited or nervous, as on meeting strangers. The patient had a normal basal metabolic rate. No other abnormalities were noted except for the fact that her hands were constantly cool, and the skin of her fingers somewhat redder than normal.

On November 23, 1932, a right thoracic ganglionectomy was performed, with resection of the first and second thoracic sympathetic ganglia. Recovery was uneventful. The patient developed a moderate Horner's syndrome. The hand became completely dry after the operation and 10°F warmer than the left.

The patient was re-examined 4 years later, and still showed the same excessive sweating in her left hand and in both feet. There was a faint but perceptible degree of perspiration in the right palm. She wrote recently that her right hand never sweat and that she was able to work very satisfactorily as a hostess in a hotel.

*Case 2* J. C., aged 23. This patient, who at the time he was first seen was a third year student of medicine, began to notice excessive sweating in the palms and fingers of his hands during the latter part of his high school years. This had become progressively worse through his medical school career. It had become embarrassing to do physical examinations on patients, and when he assisted at operations his rubber gloves would fill with sweat. When he was free from all emotional strain the condition might clear up entirely. He had tried formalin soaks, radiation of the skin and psychotherapy without benefit. Physical examination showed a healthy young adult without any abnormalities except the unusual sweating. His hands were at times distinctly colder than normal, but at other times were quite warm. As he could not afford the time needed for the usual sympathectomy, I discussed with him the possibility of blocking the sudomotor fibers by paravertebral alcohol injection. This was finally decided on, with the understanding that the nerves leading to one hand should be blocked, and a year allowed to intervene

before deciding whether to employ alcohol injection or surgery on the other extremity.

On October 6, 1933, alcohol was injected paravertebrally around the upper three thoracic sympathetic rami and ganglia on the left side, 4 cc. of 95 per cent alcohol at each level.\* This resulted in a striking Horner's sign and a hot, dry hand. The patient resumed his classwork the next morning and noticed no disagreeable effects except a barely perceptible hyperesthesia along the distribution of the upper intercostal nerves, which lasted about 1 month. The left hand remained completely dry for 6 months, and then showed the slightest possible trace of moisture (Fig 3). The Horner's sign had gradually disap-

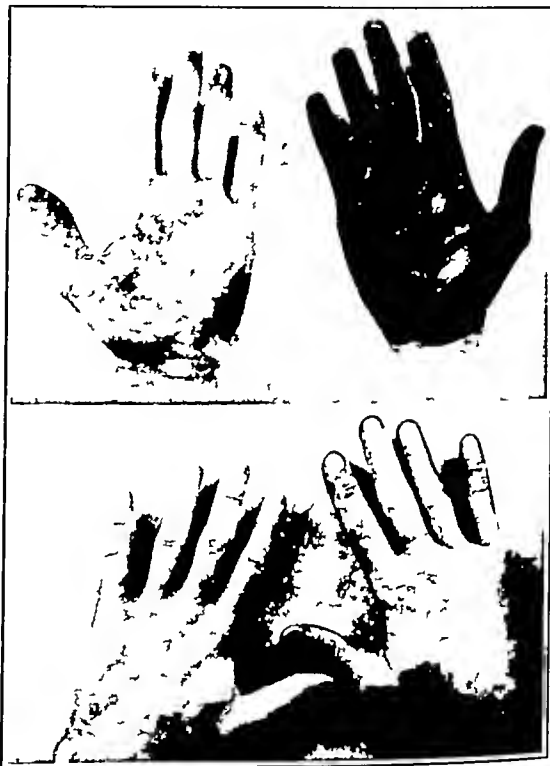

Figure 3 Photographs of the Hands of a Patient (Case 2) One Year after Paravertebral Alcohol Injection on the Left Side (Reproduced from *The Autonomic Nervous System: Anatomy, physiology, and surgical treatment* [New York, 1935] by courtesy of the publisher, The Macmillan Co.)

*There is extreme sweating on the right but only traces of moisture on the left*

peared. At the end of 1 year the patient returned for injection on the opposite side.

On November 30, 1934, a paravertebral alcohol injection was made on the right side. Again the injection caused no inconvenience, and the patient returned to his classes the following morning. No Horner's sign was produced on this side, although the sympathetic denervation of the arm appeared to be complete.

Almost 5 years have now intervened since the injection was done on the left side. The hands continue to be free from any excessive moisture. However, the patient states that in extremely hot weather his hands perspire about as much as those of a normal individual. This indicates that there has been a partial regeneration of the sudomotor fibers.

The technic of paravertebral injections is described elsewhere.<sup>11</sup>

## TULAREMIA

## Report of a Case of the Typhoidal Form

THEODORE L. BADGER, M.D.\*

BOSTON

**T**ULAREMIA is almost unknown in New England, and the rarity of its appearance here is not wholly explained. Francis<sup>1</sup> shows that up to 1937 only 4 cases had been reported from the New England States. In 1929 in North Scituate, Rhode Island, a man contracted tularemia after tearing apart three rabbits found dead on his farm. In 1929 in Massachusetts a man contracted the disease after dressing a cold-storage rabbit obtained from the Boston market. In 1931 in Claremont, New Hampshire, a person became ill after dressing two rabbits killed near-by. A fourth case occurred in 1933 in the Moosehead Lake region of Maine, where a hunter contracted the disease after skinning a red fox. No case has ever been found in Vermont or Connecticut, and none have been reported from anywhere in New England since 1933. An editorial<sup>2</sup> in this *Journal* in 1937 commented on this region's freedom from tularemia, and warned against the importation of Western rabbits to augment our own stock.

The case of tularemia here described is the second ever reported in this state and the first in the Cape Cod region. Its appearance there is felt to be significant, for this is a tick-infested region where, given rabbits infected with tularemia, the more widespread transmission of the disease might easily become established.

## CASE REPORT

The patient, a 10-year-old girl, was first seen in her home in West Falmouth on July 3, 1937, because of fever of unknown cause of 1 week's duration. Seven days before she had had a chill lasting 1 hour. This was followed by a temperature of 102° F, which rose to 103.5° F during the day. There was a slight headache, some constipation and rather more gas in the bowels than usual. Aside from these minor complaints the patient felt well. Prior to June 27 she had been perfectly well in all respects.

The recent past history presented no known contact with infectious disease, no illness during a trip to the Orient, from which she had returned a month previously, no significant association with tuberculosis, no consumption of raw milk at any time and no bites by insects or ticks. In her parents' minds the only incident of importance was that the child's Springer spaniel puppy had been quite ill with fever and cough for 3 days before the onset of her illness. This fact, however, was regarded by her physicians as unimportant and was neglected until later.

The first week of illness was characterized only by the persistence of fever from 101 to 104° F without malaise.

The patient felt well enough to go out and play as usual. The past history was irrelevant.

Physical examination, on July 3, 1 week after onset, revealed nothing of significance except a possibly enlarged spleen. The skin and mucous membrane were clear and without eruptions. The tonsils were large but without evidence of infection. No enlarged lymph nodes could be felt. The heart and lungs were clear. The pulse rate was 99, and the blood pressure 108/68. The extremities and reflexes were normal. There was no stiffness of neck or back. A Kernig test was negative. The urine had been normal on a previous examination, and the white cell count was 6000.

At the first visit the high fever, relatively slow pulse, low white-cell count and probable enlargement of the spleen led to a tentative diagnosis of typhoid or paratyphoid fever. Subsequent laboratory studies failed to substantiate this diagnosis. The Widal test, questionably positive at first, was later three times negative.

On July 12, because the fever continued to range from 101 to 103.5° F, the patient was transferred to the Massachusetts General Hospital for study. Persistently high fever to 103° F and a brisk nosebleed were the sole significant clinical observations during her 4-day hospital stay. She was seen by two consultants, who found her physical examination essentially normal. At no time were skin lesions seen. No lymph nodes were enlarged. The spleen was never thought to be enlarged after the first examination. There were no localizing signs of any sort. The patient was never prostrated and retained a remarkable sense of well being.

On July 16 she was sent home after completion of studies, undiagnosed. Her fever fell by lysis and permanently reached normal September 1, 9 weeks and 3 days after its abrupt onset. Blood collected on the day of discharge was sent to the National Institute of Health in Washington, District of Columbia, to be tested for typhoid fever, undulant fever and tularemia. The blood was reported positive for tularemia in a titer of 1:1280. It was negative for typhoid and undulant fevers.

The white-cell count on June 30 was 6000 and on July 3 had risen to 17,000. On July 12 the hemoglobin was 40 per cent and the red-cell count was 4,530,000. The white-cell count had fallen to 11,400, with 74 per cent polymorphonuclears, 20 per cent lymphocytes, and 6 per cent mononuclears. There was moderate achromia. The corrected sedimentation rate was 0.7 mm per minute and the hematocrit 37.7 per cent. A blood culture taken July 12 showed no growth after incubation for 12 days. A catheter specimen of urine showed no growth. Daily urine specimens were negative except for a few red blood cells on one occasion. Stool examination on July 13 showed no pathogenic organisms. No parasites or amebae were seen on warm stool examination. A throat culture on July 12 showed no hemolytic streptococci. An electrocardiogram on July 12 was within normal limits, and an x-ray film of the chest taken the next day showed the lung fields to be clear. The heart, mediastinum and diaphragms were not remarkable.

\*Assistant in medicine, Harvard Medical School; junior visiting physician, Boston City Hospital.

Medical measures of control are unsatisfactory in the more severe cases

Sympathetic denervation of the arm and leg offers a safe and certain cure. The operation results in warm and dry extremities. If care is taken to avoid the ocular fibers (the section of which results in Horner's syndrome) and to leave the highest portion of the lumbar chain in the male intact (in order to preserve the power of ejaculation), there are no annoying sequelae.

## DISCUSSION

DR. DONALD MUNRO, Boston. There are two things I should like to emphasize. In the first place, I doubt if there is another as skillful a surgeon of the sympathetic nervous system working today as Dr. White, and his description of this operation, which looks and reads so simply, should not be allowed to lead us astray and into thinking that we can do one before breakfast, as it were, because it is not an easy operation to do. Secondly, we should all realize that we have listened to a presentation which we can accept at its absolute face value, and concerning which discussion is unnecessary.

DR. JOHN HOMANS, Boston. I should like to ask Dr. White whether there is any such thing as excessive sweating without at the same time some evidence of vasomotor spasm. Also, in making a diagnosis is it necessary to be sure that one can secure full vasodilatation by a novocain block or in some other way, before using this operation to prevent sweating?

DR. WILLIAM J. MIXER, Boston. I have watched Dr. White's cases with the greatest interest. The results are little short of marvelous. No one would do this operation for a person who sweats only moderately. There are not very many of these bad cases, but those patients who really sweat profusely are perfectly wretched. They will go to almost any length to get relief. Here is an operation which gives them positive relief with very little risk, an operation which has to be done with a good deal of care, and at the same time one which in proper hands carries a very low mortality.

DR. WHITE (closing). To answer Dr. Homans's first question: most of these patients had cold as well as moist hands, but at least one had hands as warm as those of a normal individual. So far as testing with novocain goes, I think the anatomical arrangement of the sweat fibers is so constant that, if you are doing the operation merely to stop the sweating, there is no need to do a novocain block. We did it in our early cases but we have not used it since then. However, if it is a case of cold as well as sweaty hands, and particularly if there is any scleroderma-type change, it is best to test and see how much vasodilatation can be obtained by paralyzing the vasoconstrictor nerves.

peared in the town of Falmouth. It appears probable that the child's dog killed or ate one of these imported rabbits with tularemia, or was bitten by an infected tick. In view of the evidence presented, it seems logical to suppose that the puppy's illness was tularemia. The transmission to the child was apparently direct, since no other source could be found.

#### HISTORICAL BACKGROUND

Tularemia as we know it was originally confused with bubonic plague, both clinically and bacteriologically. Wherry<sup>4</sup> in 1908, when he was bacteriologist of the San Francisco Board of Health, published an excellent review of this problem. His account may be briefly summarized as follows:

In 1903, three years after the first appearance of bubonic plague in this country in San Francisco, Assistant Surgeon Rupert Blue, United States officer in charge of plague suppression, suspected that ground squirrels, which were dying in large numbers, were afflicted with the same disease as were human beings, and were responsible for its conveyance to them in the widely scattered areas from which it was being reported. That the squirrels had a plague-like disease was clear, but that they transmitted it directly to human beings was not proved. Soon, however, a boy of ten in Los Angeles was bitten on the finger by a sick ground squirrel which he picked up near his home. Four days later he became ill with a plague-like disease, thought to be bubonic plague. From the suppurating glands of this boy, an organism like the bacillus of plague was cultured. As a result, until 1909 squirrel plague (now known as tularemia) and human plague were thought to be the same disease. In 1910, however, Post-Assistant Surgeon George W. McCoy,<sup>5</sup> of San Francisco, published a paper showing that there was a distinct difference between bubonic plague and squirrel plague, and that although the pathological and bacteriological findings were similar, they were not identical.

In 1911 McCoy and Chapin<sup>6</sup> identified the organism of squirrel plague, cultured it, transmitted it to guinea pigs and named it *Bacterium tularense* (*Pasturella tularensis*), after Tulare County, California, where the disease was first observed.

In 1914 Wherry and Lamb<sup>7</sup> reported the first case of human infection with the organism discovered by McCoy and Chapin. This was a case of ulcerative conjunctivitis with lymphadenitis from which organisms identical with *Pasturella tularensis* were recovered. Since 1914 tularemia has been shown to be widespread throughout the United States, with the exception of New England.

#### CLINICAL TYPES

The literature is filled with clinical, pathological and bacteriological studies of tularemia, but Francis<sup>8-10</sup> has probably contributed most to the early clarification of the disease in its various aspects. He describes four clinical types, as follows: *Ulceroglandular*. The primary lesion at the site of inoculation is a papule of the skin. This papule later ulcerates and is accompanied by enlargement and often ulceration of the regional lymph nodes. *Oculoglandular*. The primary lesion is in the eye (transmitted from the hands) and is accompanied by enlargement of the regional lymph nodes. *Glandular*. No primary lesion is found at the site of inoculation, but there is fever, and infected regional nodes are found. Often there is a generalized adenopathy. *Typhoidal*. Persistent fever is the outstanding feature. There is no primary ulceration and no detectable lymph-node enlargement.

It is with the typhoidal type that we are particularly interested. This type is so named because of its similarity to typhoid fever, with which it is often confused. At other times it passes for fever of unknown origin, septic infection and influenza. The pulmonary lesions in the typhoidal form have led to the diagnosis of tuberculosis or of pneumonia. The cross-agglutinations with *Brucella abortus* and *Br. melitensis* have caused it to be called undulant fever. A clinical diagnosis of typhoidal tularemia is rarely possible. Where persistent, unexplained fever exists, however, specific agglutination tests offer the only clue to diagnosis.

The onset of typhoidal tularemia is abrupt and without warning, and is marked by chills, fever, headache, vomiting, sweating, prostration or joint pains. There is an initial rise of temperature, followed by remission of the fever and symptoms for two or three days, then a return of the fever, which is constantly elevated or spiking, for from three to ten weeks, disappearing by lysis.

It is of interest that patients may retain a sense of well being throughout the course of a typhoidal tularemia of several weeks' duration with persistent fever, however, prostration is usual. Nosebleeds during the second and third weeks are not uncommon. Headache may be severe or lacking. The white-cell count is usually low in the early stages, later rising as high as 16,000. Foshay<sup>11</sup> has shown in a series of 400 unselected cases of acute tularemia that the typhoidal type is a generalized infection from the start, with minor cutaneous or regional lymphatic involvement, or more commonly none at all. In the other three types of the disease the lymphatic system appears to bear the brunt of the attack. Multiple lesions in the deep

Typhoid agglutination was partially positive on a specimen taken July 3 but negative on July 6 and 12 and October 9. Tests for paratyphoid fever were negative on four occasions. Blood taken for undulant fever was negative on July 3. Blood drawn July 16 was negative for undulant fever but positive for tularemia in a titer of 1:1280. Agglutination tests on October 9 were negative for undulant fever, negative for the Weil-Felix reaction and positive for tularemia in a titer of 1:1280.

The tuberculin test was negative to 1 mg. of old tuberculin. A blood Wassermann test was negative. A skin test done on October 9 for tularemia, with a suspension of killed *Pasteurella tularensis* provided by Dr. Lee Foshay, was strongly positive.

It was due solely to the fact that the child's parents referred again and again to her sick dog that the tularemia agglutination was done at all. A young Springer spaniel puppy, which had been in the Middle West during its early months, had been given to the patient a month before the onset of her illness. The dog had been well until three days before the patient fell ill. At that time it became sickly and feverish and coughed, recovering in three days. Since it was an affectionate puppy its contact with the patient was constant and close. She had, however, received no bites or scratches from the dog, or tick or flea bites at any time before her illness. Following the diagnosis of tularemia, blood was collected from the dog on August 4, five weeks after its illness, and was found positive for tularemia in a dilution of 1:40. The source of the dog's infection was not found, but may have been a tick bite or the eating of a rabbit which had died of tularemia.

This is the only case on record where definite relation between the disease in a dog and a human being has been shown. Experimentally tularemia has been produced in dogs, and Francis<sup>1</sup> reports 1 case following a dog bite, but the dog was never shown to have had the disease. Puppies are more easily infected than adult dogs. Although a titer of 1:40 is one of low dilution, it may not go higher than this in human beings known to have had tularemia.<sup>1</sup> The appearance of a positive agglutination in both child and dog in the case reported would seem to be more than coincidence. Infection of the child was probably by the dog's saliva from hand to mouth.

#### IMPORTATION OF WESTERN RABBITS TO CAPE COD

In 1936 the Division of Fisheries and Game of the Massachusetts Department of Conservation<sup>3</sup> authorized the importation into this state of cottontail rabbits from the West. The director of the division, it was announced, had conferred with officials of the New York Conservation Department, which had for a number of years been importing cottontails from the West, and it had been

planned to make the Massachusetts system of importation conform as closely as possible to that employed in New York. Plans were being formulated, it was stated, for the importation of a considerable number of cottontail rabbits during 1937.

Table 1 *Cottontail Rabbits Released by the Division of Fisheries and Game*

TOWN	NO. OF RABBITS	DATE
Harwich	5	March 31 1937

Wellfleet	5	March 31 1937
Falmouth	8	March 31 1937
Barnstable	6	March 31 1937
Total	33	

During the spring of 1937, western cottontail and jack rabbits were released on Cape Cod, the former by conservation officers and the latter by local sportsmen's clubs, as shown in Tables 1 and 2.\*

J. Arthur Kitson, in charge of propagation in Massachusetts, stated in a letter dated December 8, 1937, that all rabbits received dead were examined by a competent pathologist and that no tularemia was found. But in none of these examinations were guinea pigs inoculated with tissue.

Table 2 *Jack Rabbits Released by Sportsmen's Clubs*

TOWN	NO. OF RABBITS	DATE
Harwich	12	Middle of May 1937
Provincetown	16	May 24 1937
Barnstable	14	June 21 1937

Wellfleet	12	May 4 1937
Dennis	24	Latter part of May 1937
Total	90	

(For the guidance of those especially unfamiliar with tularemia, the disease is altogether too easily overlooked in the gross. Guinea-pig inoculation has been shown to be the only sure method of diagnosis and identification.)

With these facts in mind, it seems particularly significant that this young child, with no known source of infection or trauma or bites, developed tularemia in a region where the disease had never been seen. It is also significant that the common wood tick, *Dermacentor variabilis*, is prevalent on Cape Cod, and that these ticks, feeding chiefly on small rodents during the larval and nymphal stages, feed indiscriminately on both men and animals during the adult stage. Thus the danger of tick-borne tularemia is constant in this region.

It is noteworthy that three months after the release of Western cottontail rabbits in the Falmouth district this isolated case of tularemia ap-

\*Information supplied by J. Arthur Kitson.

## SPECIFIC THERAPY

Symptomatic treatment of tularemia still holds the place it should in any acute infection, but specific serum now offers the safest and surest method of treatment. Intravenous chemotherapy with arsenicals<sup>14</sup> and iodides has proved of no value. X-ray therapy<sup>15</sup> for primary local lesions has been thought to shorten the course of the disease if applied in the first four days of the disease, but is of doubtful value. Immunotransfusions have been shown of value, but suitable donors are difficult to find. Foshay<sup>19</sup> reports a case of acute tularemia treated as effectively by immune serum as by antiserum.

The antiserum developed by Foshay<sup>16-18</sup> is of specific therapeutic value. There is, with its use, a definite antitoxic action, with a fall in temperature, disappearance of symptoms and regression of lymph nodes, if present, and healing of primary lesions. The usual dose is 30 cc intravenously for adults, although an additional 15 cc may be given if improvement fails to appear. Severe cases with complications may receive up to 60 or 70 cc. Serum reactions may follow the administration. Goat serums<sup>16</sup> have proved effective in the past. Surgery should be used only for the incision of acute suppurating glands.

## PROPHYLAXIS

The prevalence of the disease among wild rabbits makes its eradication impossible, but those who handle or dress them should protect themselves with rubber gloves and frequent, careful washing of the hands. Possibly hunters and market men who handle rabbits from grossly infested areas should be immunized. Foshay urges this for those doing laboratory work or animal experimentation, feeling that it is the only prophylactic measure of value.

## SUMMARY

A case of tularemia contracted in Falmouth, Massachusetts, is reported in a girl of ten. It is

the second case ever reported in Massachusetts and the fifth in New England.

No known source for this infection could be found except the child's young Springer spaniel puppy. The dog was ill three days before the abrupt onset of the infection in the child, and its blood serum later agglutinated *Past tularensis*, as did the child's.

Three months preceding the appearance of this case Western cottontail and jack rabbits were shipped to Cape Cod. Eight of these rabbits were released in the vicinity of Falmouth.

The conclusion seems justified that the dog killed or ate a Western rabbit that had tularemia, became ill himself and transmitted the disease to the child.

If tularemia has become established on tick-infested Cape Cod, such a condition of affairs is of extreme public-health importance.

A brief review of the historical and clinical aspects of tularemia is presented.

264 Beacon Street.

organs and lungs characterize the typhoidal type

The mortality rate of the typhoidal type of tularemia Foshay found to be approximately 40 per cent, nearly four times that of other clinical types, and the incidence of complicating pneumonia four times the average in the other three types

Septicemia, Foshay showed, occurred in 1 out of every 17 cases without forewarning. The chief clinical signs of septicemia are progressive enlargement of the liver and spleen, sometimes with increasing jaundice and septic fever. Hyperpnea and cyanosis, meningeal and cerebral involvement, diarrhea, progressive bronchopneumonia, acute renal involvement, pleurisy, pericarditis and peritonitis may appear. Septicemia is the chief cause of death attributable to tularemia alone, but pneumonic lesions were shown to be present in half of Foshay's fatal cases

#### SOURCES OF HUMAN INFECTION

Human beings become infected with *Past tularensis* by contact with the raw flesh or blood of infected animals, by the bites of blood-sucking insects and flies and by the eating of insufficiently cooked infected meat. Francis<sup>1</sup> in a recent report pointed out that twenty varieties of wild life contract and transmit tularemia. The cottontail rabbit, the snowshoe hare and the jack rabbit account for 90 per cent of all human infections

Most infections occur through wounds or abrasions in the skin, most frequently of the hands, but *Past tularensis* can penetrate the unbroken skin. Wood ticks, dog ticks, horseflies, houseflies, fleas and bedbugs have been shown to cause infection. Tree squirrels and opossums have been responsible for cases of tularemia. One case each has been reported from skinning a sage hen, coyote, deer, red fox and bull snake. Two cases each came from contact with quail, ground hog and skunk. Two patients had been scratched by cats. Single cases have followed from the bites of the cat, skunk, coyote, tree squirrel, opossum, hog, lamb, white rat and dog. Contamination in the latter group of cases is believed by Francis to be from the animals' mouths. Market men, hunters and meat dressers are most frequently affected, usually with the ulcerative type. Laboratory workers have frequently been infected, with a high incidence of the typhoidal type of the disease

#### NON-CONTAGIOUSNESS AND IMMUNITY

According to Francis<sup>1</sup> there is no record of transfer of infection from man to man. Doctors, nurses and others attendant on the sick have not contracted the disease. One attack confers a lasting immunity. Blackford,<sup>12</sup> however, reports 2

cases of ulcerative dermatitis where living organisms were obtained five to twenty-one months after the initial infection. Foshay, discussing Blackford's paper, says that relapses are not frequent but may be seen weeks or months after the initial infection. These relapses, he believes, are due to residual living bacteria in the tissues and most commonly occur in cases with ulcerating skin lesions and chronically suppurating lymph nodes

#### AGGLUTINATION TESTS

Francis<sup>8</sup> states that there is apparently a complete absence of agglutinins for *Past tularensis* during the first week of the disease. The appearance of specific agglutinins occurs sometime in the second week, with an abrupt rise in titer in the third week, reaching its maximum in the fourth to seventh week. After the eighth week the titer usually falls, but positive agglutinins have been known to remain as long as twenty years

Serums from cases of tularemia may show agglutinations with *Br abortus* and *Br melitensis*. Francis<sup>8</sup> reports that of 579 such serums 129 showed agglutination with *Br abortus* and *Br melitensis*, while 441 failed to cross-agglutinate. Many serums showing no cross-agglutination had the highest titers (1:1280 to 1:2560) against *Past tularensis*. Serums from tularemia patients agglutinate *Past tularensis* in much higher titer and much more quickly than they do *Br abortus* or *Br melitensis*. Serums from cases of undulant fever may show cross-agglutination with *Past tularensis*. Of 93 such serums, 31 showed some degree of cross-agglutination

Foshay<sup>10</sup> recognizes cross-agglutination reactions between tularemic serums and those from cases of Rocky Mountain spotted fever. He finds that tularemic animal serums invariably show a positive Weil-Felix reaction, but those of human subjects rarely do. He has recorded only 4 cases in which human serums have given such a reaction

#### SKIN TESTS

Foshay<sup>13</sup> has shown that an intradermal test done with a detoxified bacterial suspension of *B tularensis* is the earliest diagnostic aid for determining the presence of tularemia. The allergic skin response is specific and reliable. Positive reactions occur as early as the fourth day of illness, almost a week before agglutinins appear in the blood. He has demonstrated that positive skin reactions are constant in the presence of tularemia, but do not occur in normal persons or in the presence of other acute infections

## SPECIFIC THERAPY

Symptomatic treatment of tularemia still holds the place it should in any acute infection, but specific serum now offers the safest and surest method of treatment. Intravenous chemotherapy with arsenicals<sup>14</sup> and iodides has proved of no value. X-ray therapy<sup>15</sup> for primary local lesions has been thought to shorten the course of the disease if applied in the first four days of the disease, but is of doubtful value. Immunotransfusions have been shown of value, but suitable donors are difficult to find. Foshay<sup>19</sup> reports a case of acute tularemia treated as effectively by immune serum as by antiserum.

The antiserum developed by Foshay<sup>10-18</sup> is of specific therapeutic value. There is, with its use, a definite antitoxic action, with a fall in temperature, disappearance of symptoms and regression of lymph nodes, if present, and healing of primary lesions. The usual dose is 30 cc intravenously for adults, although an additional 15 cc may be given if improvement fails to appear. Severe cases with complications may receive up to 60 or 70 cc. Serum reactions may follow the administration. Goat serums<sup>18</sup> have proved effective in the past. Surgery should be used only for the incision of acute suppurating glands.

## PROPHYLAXIS

The prevalence of the disease among wild rabbits makes its eradication impossible, but those who handle or dress them should protect themselves with rubber gloves and frequent, careful washing of the hands. Possibly hunters and market men who handle rabbits from grossly infested areas should be immunized. Foshay urges this for those doing laboratory work or animal experimentation, feeling that it is the only prophylactic measure of value.

## SUMMARY

A case of tularemia contracted in Falmouth, Massachusetts, is reported in a girl of ten. It is

the second case ever reported in Massachusetts and the fifth in New England.

No known source for this infection could be found except the child's young Springer spaniel puppy. The dog was ill three days before the abrupt onset of the infection in the child, and its blood serum later agglutinated *Past tularensis*, as did the child's.

## NEOPLASMS OF THE TESTIS\*

## A Study of the Results of Orchidectomy, With and Without Irradiation

HUGH CABOT, MD,† AND JOSEPH BERKSON, MD‡

ROCHESTER, MINNESOTA

THIS paper originated as the result of the return to the Mayo Clinic, for other causes, of several patients who had been operated on for highly malignant tumors of the testis and who appeared to have survived longer than was considered quite reasonable. Now it is very difficult and probably impossible to determine the accepted standard opinion as to the expectancy of life for victims of this malady. The literature lends but feeble assistance to such endeavors, since the reports are made in such form as to be quite difficult of comparison. Commonly a certain percentage of patients are stated to have survived operation or irradiation or both but without clear indication of the duration of survival. Again, an array of figures is presented on patients said to have had a tumor of the testis, but it is not clear what the word "tumor" is intended to convey. However, we think it may safely be suggested that average expert opinion holds that practically all tumors of the testis are malignant, that the malignancy of most of them is of relatively high grade, with the exception of the adult teratoma, that the disease is very fatal and that survival beyond five years is uncommon, that irradiation in competent hands has materially extended the life expectancy, with or without orchidectomy, and that the relatively recent discovery of the presence of anterior pituitary-like substances in the urine is of both diagnostic and prognostic importance.

We shall be able to submit statistical data showing the ultimate result in a relatively large number of cases. Particular attention is here called to the fact that in the series analyzed in this study for survival and to be presently referred to, 98 per cent of the patients were followed for at least five years. Unfortunately we shall not be able to offer any evidence on the value, either in diagnosis or prognosis, of the discovery of anterior pituitary-like substances in the urine. Our experience with this method is still confined to a group of cases too small to warrant any definite conclusions.

This study is based on an analysis of 363 cases seen at the Mayo Clinic between January 1, 1910,

and January 1, 1937. The mean age of these patients was 36.2 years, the youngest being seven years and the oldest eighty-four years. It is commonly stated that in something like 80 per cent of cases the disease occurs between the twentieth and fortieth years. Our figures tend to show a somewhat higher range. Sixty-two per cent of the patients were between the ages of twenty and forty, and 20.9 per cent between forty and fifty. This is a somewhat higher figure than is commonly given.

Of the 363 patients, 148 were seen in the first instance at the Mayo Clinic, 215 came to the clinic only after they had been treated or a diagnosis had been made elsewhere, and they were

Table 1 Summary of Treatment in All Cases, with a Listing of the Tissue Available for Re-examination

TREATMENT	NO. OF CASES	TISSUE AVAILABLE FOR HISTOLOGICAL RE-EXAMINATION

Without previous operation elsewhere†	50	0	6
Totals	363	156	12

\*For example, orchidectomy, exploration.

†Except possibly biopsy.

sent primarily for irradiation, many of them having very extensive metastases. Of the 148 first seen at the clinic, 142 were treated by orchidectomy, with or without irradiation. Of the 215 other patients, all were treated at the clinic by irradiation, and 165 of them had had operation elsewhere. This distribution is shown in Table 1.

## ANALYSIS OF CASES TREATED BY ORCHIDECTOMY WITH OR WITHOUT IRRADIATION

Since the evidence in regard to patients coming to the clinic after operation elsewhere was necessarily incomplete, we have thought that the purposes of this paper would be best served by a careful analysis of the 142 cases in which orchidectomy was performed at the clinic and in which all the pathological examinations were made there.

\*Read before the meeting of the American Medical Association, San Francisco, June 13-17, 1938.

†Professor of surgery, University of Minnesota Graduate School, Minneapolis; consulting surgeon, Mayo Clinic, Rochester.

‡Medical statistician, Mayo Clinic.

Table 2 shows the pathological diagnoses made on a recent check of the specimens.\* The most striking point to be observed is the relatively high percentage of neoplasms classified as seminoma (59.2 per cent). It should be stated here that we

†Teratoma 4 embryos, 3 sarcoma 1 no histological diagnosis, 1 Three cases were not recently reviewed

regard seminoma as a variety of carcinoma, and are still neutral in our opinion as to whether it is a separate entity, a view long championed by

may be finally determined. The other point clearly brought out by this table is the high grade of malignancy of the group classified as seminoma when malignancy is rated by the examination of the histologic specimen. It will be noted that all 84 of these cases are classified as Grade 4. This is in some, though not very striking, contrast to those classified as adenocarcinoma or adenocarcinoma with teratoma.

### Three-, Five- and Ten-Year Survivals

These figures, according to type of lesion and irradiation, are presented in Table 3. It is at once evident that the survival rate of patients having so-called seminoma is very much higher throughout all these periods than that of patients having tumors classified as carcinoma, irrespective of the use of irradiation. Among the patients with carcinoma, there appears to be a higher survival rate for the three- and five-year periods in those treated

Sixty-two per cent of the patients were between the ages of twenty and forty, and 20.9 per cent between forty and fifty. This is a somewhat higher figure than is commonly given.

Of the 363 patients, 148 were seen in the first instance at the Mayo Clinic, 215 came to the clinic only after they had been treated or a diagnosis had been made elsewhere, and they were

sent primarily for irradiation, many of them having very extensive metastases. Of the 148 first seen at the clinic, 142 were treated by orchidectomy, with or without irradiation. Of the 215 other patients, all were treated at the clinic by irradiation, and 165 of them had had operation elsewhere. This distribution is shown in Table 1.

## ANALYSIS OF CASES TREATED BY ORCHIDECTOMY WITH OR WITHOUT IRRADIATION

Since the evidence in regard to patients coming to the clinic after operation elsewhere was necessarily incomplete, we have thought that the purposes of this paper would be best served by a careful analysis of the 142 cases in which orchidectomy was performed at the clinic and in which all the pathological examinations were made there.

Read before the meeting of the American Medical Association, San Francisco, June 13-17, 1938.

regard seminoma as a variety of carcinoma, and are still neutral in our opinion as to whether it is a separate entity, a view long championed by

may be finally determined. The other point clearly brought out by this table is the high grade of malignancy of the group classified as seminoma when malignancy is rated by the examination of the histologic specimen. It will be noted that all 84 of these cases are classified as Grade 4. This is in some, though not very striking, contrast to those classified as adenocarcinoma or adenocarcinoma with teratoma.

### Three-, Five- and Ten-Year Survivals

These figures, according to type of lesion and irradiation, are presented in Table 3. It is at once evident that the survival rate of patients having so-called seminoma is very much higher throughout all these periods than that of patients having tumors classified as carcinoma, irrespective of the use of irradiation. Among the patients with carcinoma, there appears to be a higher survival rate for the three- and five-year periods in those treated

Chevassu but not yet finally determined. It is not impossible that with the accumulation of evidence in regard to the presence and quantity of anterior pituitary-like hormonal substances in the urine, the question of the origin of this tumor

by orchidectomy without irradiation than in those treated by orchidectomy with irradiation. These figures, however, are somewhat misleading, since the number of patients not treated with irradiation is relatively small and hence, statistically, relatively unreliable. Moreover, the group of patients given irradiation contained a much larger per-

Excp 17 cases in which tissue was no longer available for examination.

centage of those with metastases (42 per cent) than did the group without irradiation (8 per cent). It is interesting to note that at the end of ten years there is no substantial evidence that the survival rate has been affected by irradiation.

Turning now to the patients with seminoma treated by orchidectomy, there is a substantial difference, favorable to the group that had irradiation, in the survival rates for the three- and five-year periods. On the other hand, there is no clear evidence that the survival rate at the end of the ten-year period has been significantly influenced by irradiation. The more favorable three- and five-year rates for the group that had irradiation is the more impressive when we note the facts with respect to metastases. This group had a somewhat larger percentage of known metastases (26 per cent) than the patients treated by orchidectomy without irradiation (15 per cent). Thus the evidence in favor of the value of irradiation for patients with this lesion seems substantial, and it is a fair conclusion that the survival rate for the three- and five-year periods is improved by this treatment.

The situation according to type of lesion and the known presence or assumed absence of metastases is also shown in Table 3. It should, of course, be understood that many of the patients in whom metastasis was not noted may be assumed to have had some extension of the disease to the lymph nodes, which were nevertheless not sufficiently enlarged to be palpable. In fact, the diagnosis of metastasis by physical examination, except where the growth is massive, is notoriously uncertain. On the other hand, Table 3 clearly shows that the prognosis at all three periods is distinctly better for patients in whom metastasis is not known to be present. Perhaps the most outstanding fact here shown is the extraordinarily high survival rate (75 per cent) of patients with seminoma but without known metastasis over the five-year period. Again, the finding of a lower survival rate for the groups with known metastasis is made more striking if the relative amount of irradiation is considered. The percentage of patients with irradiation was higher in the group with metastasis in respect to both the carcinomas and the seminomas. Despite this, the survival rates were considerably lower among individuals showing obvious metastasis, demonstrating how serious a prognostic factor is the observation of metastasis.

Survivals according to type and known duration of the lesion before treatment are likewise shown in Table 3. It has long been assumed that relatively early diagnosis is of great importance in prognosis. Table 3 does not very clearly bear out

this view. In the group classified as carcinoma, the survival rate over the three-, five- and ten-year periods is somewhat higher for those patients in whom the known duration was less than a year. On the other hand, the difference is small and of doubtful statistical significance.

In regard to the cases of seminoma, the situation is even more confusing. It will be noted that in this group the lesions were divided into those with duration of less than six months, of six months to one year and of one year or more. There is a regularly progressive difference in the survival rates unfavorable to those with lesions of short duration among these three groups. As between the group with lesions of less than six months' duration and that with lesions of six months to a year's duration, the difference is substantial,

Table 4 Twenty Year Survivals

CASE NO.	YEAR OF TREATMENT	AGE	PATHOLOGICAL REPORT	LAST REPORT	DURATION OF LIFE FOLLOWING TREATMENT
		yr			yr
1	1910	36	Seminoma no metastasis	Living	27
2	1910	24	Adenocarcinoma Grade 3 (not a seminoma and apparently not in a teratoma) no metastasis	Living	26
3	1911	27	Adenocarcinoma Grade 2 (not a seminoma) no metastasis	Living	26
4	1912	46	Seminoma no metastasis	Dead leukemia	25
5	1912	38	Seminoma no metastasis	Living	25
6	1917	52	Seminoma no metastasis	Living	20

between the latter and the group with lesions of a year or more the difference is meager. On careful consideration, we think that the apparently less favorable result obtained for the group with lesions of less than six months' duration is probably more apparent than real. One of us (J. B.\*) has previously pointed out that in studying the life expectancy of patients with cancer in other regions, the same apparently unfavorable result of early diagnosis appeared. This is perhaps due to the fact that the patients who appear relatively early are likely to have what we are pleased to call very malignant lesions. In this series, for instance, we find some substantiation of this theory in the fact that the groups with lesions of longer duration contain a somewhat smaller percentage of patients showing metastasis. This is of course another way of saying that the relation of the cancer to the host is weighted in favor of the cancer. The patients who do not present themselves for a year or more thus represent a certain survival group who, for some mysterious reason, are better able to resist the disease. Nevertheless,

Unpublished data

so far as the figures go they suggest that we must consider the possibility that very early diagnosis is not of the overwhelming importance which has been suggested

### *Twenty-Year Survival*

Finally, Table 4 shows a group of 6 cases in which the patients survived more than twenty years. Of the lesions, 4 were classified as seminomas and 2 as adenocarcinomas. None of the patients with seminoma had known metastasis. The adenocarcinomas were classified respectively as Grade 3 and Grade 2 lesions, these patients also had no known metastases. These cases are presented only as evidence that, in the absence of metastasis, a small group of patients will survive even without irradiation.

### SUMMARY

This study is based on a follow-up of 363 patients with tumors of the testis seen at the Mayo Clinic between 1910 and 1937. Of this number, 215 were seen only after the diagnosis had been made elsewhere, and in some cases after part of the treatment had been carried out. In order to deal only with patients whose condition was completely observed and treated at the clinic, cases of this type were selected for careful study.

Of these 142 patients, in 59.2 per cent the tumors were classified as seminomas, in 34.5 per cent

as adenocarcinomas of various forms, in 6.3 per cent as miscellaneous types of cancer.

The ten-year survival rate of patients having seminoma was found to be relatively high as compared with what is, we think, the commonly held opinion. Thus, 47.4 per cent were alive and apparently well ten years or more after treatment. This should be compared with the survival rate of the patients classified as having carcinoma, which was 26.4 per cent.

The survival rate of seminoma is much higher than that of carcinoma at five years, being 67.7 per cent as compared with 29.3 per cent.

Irradiation seems to materially improve the three- and five-year survival rates for seminoma. Thus, of the patients treated by orchidectomy followed by irradiation, the survival rate at three years was 80.0 per cent, as compared with 68.4 per cent of those not treated by irradiation. At five years the survival rate was 71.1 per cent of the irradiated cases, as compared with 58.8 per cent of those not so treated. Irradiation does not appear to have any important effect on the survival rate at ten years or over. Of the patients treated by irradiation, 47.9 per cent lived more than ten years, as compared with 46.7 per cent of those not so treated.

Of these 142 patients, 6 lived twenty years or more, 2 had carcinoma and 4 had seminoma, and none were treated by irradiation.

## SURVEY OF ALCOHOLIC PATIENTS ADMITTED TO THE BOSTON PSYCHOPATHIC HOSPITAL IN 1937\*

JOHN B. DYNES, M.D.†

BOSTON

THE alcoholic patients admitted to the Boston Psychopathic Hospital during 1937 comprised almost one fifth of the total admissions. This is a marked increase over 1927 (during the Prohibition Era), when such patients numbered approximately one tenth of admissions. In 1937, patients having serologic syphilis totaled only 8.4 per cent of admissions, while disorders diagnosed as dementia praecox and manic-depressive psychosis numbered approximately 15 and 16 per cent, respectively. Alcoholic patients present points of interest other than their gross number, and it is primarily with these in mind that this survey was undertaken.

In 1937, 382 alcoholic patients were admitted to

the hospital, their cases were diagnosed as shown in Table 1.

Table 1 Diagnoses

DIAGNOSIS	NO. OF CASES		
	MEN	WOMEN	TOTAL
Alcoholism without psychosis	123	27	150

Unpublished data

lagra, or only 10 per cent of the total alcoholic admissions. With neuritis we assume that there has been vitamin deficiency resulting finally in the clinical syndrome of the disease. This is true also of pellagra. It seems strange that more patients did not develop clinical manifestations of both these disturbances, as the dietary history was definitely at fault in many more cases than developed these diseases. It is of interest that only 1 patient in the series had a gastric ulcer—a low incidence which may have no significance for our study.

The urine examinations showed evidence of some form of abnormality (albumin, sugar, white cells, red cells or casts) in 250 cases (68 per cent). In many cases the abnormal findings cleared before the patient had left the hospital.

Eighty-five patients (22.0 per cent) had been in the hospital on previous occasions. Eighty-four had a history of previous psychotic disorder due to alcohol, with no hospital admission. All the patients gave a history of drunkenness on previous occasions. In 5 cases no information as to previous alcoholic disorder was available.

The mental status of the patients in this series shows certain factors of interest. The classic description of a patient with delirium tremens is that of an individual who is fearful and tremulous, and has periods of delirium and confusion associated with visual hallucinations of animals or insects, usually dogs, snakes, rodents or elephants. In this series only 57 patients exhibited any evidence of fear. Visual hallucinations of dogs and insects were the most frequent, occurring in 15 patients. Visual hallucinations of snakes occurred in 14, and those of rodents in only 1, in contrast to the assumed frequency of the latter. Horses appeared in 10 cases, while other animals not specified were seen in 9. Faces were seen by 10 patients, and flashes of light by 10. Birds, cats or dead bodies were noted in 5 cases. Elephants were seen by 4 patients, only 1 patient saw a pink elephant, and in this case the hallucination occurred as a retrospective falsification. Lions and tigers were seen by only 2 patients, whales were seen by 1 and a hippopotamus by 1. There was no correlation between the size of the animal and the duration of the delirium. Hallucinations of smell were present in only 3 cases. Lilliputian hallucinations were experienced by 3 patients. In only 1 case was there an occupational delirium. Forty-eight patients believed that hostile gangs or police were chasing them, the sensation being usually accompanied by visual hallucinations.

Accurate information concerning the duration of the psychosis prior to entry was unavailable, but the duration of mental symptoms after reach-

ing the hospital is shown by our own records. In 198 cases the symptoms had disappeared before entering the hospital. In 72 they were considered chronic, that is, they persisted after a ten-day observation period. In 63 cases they lasted one day, in 25 two days, in 11 three days, in 2 four days, in 1 five days, in 3 six days, and in 1 seven days. The longest episode of delirium tremens in the hospital was seven days. In the great majority of cases the symptoms had either cleared before entry or lasted only one or two days after it. The type of treatment seemed to have little influence on the duration of the psychosis. Some patients who received no drugs or other form of medication cleared as soon as those receiving sedative drugs. Paraldehyde in doses of 3 to 20 cc. was used most frequently, and was of considerable value in the management of acutely excited and delirious patients.

Depression was a frequent symptom, occurring in 89 patients (23.0 per cent). Forty-six of these had attempted suicide while under the influence of alcohol, and 17 others made suicidal threats. Twenty-six patients were depressed without previous suicidal attempts or threats of suicide. The most frequent precipitating factor was domestic difficulty. This may be an important disturbing element, but in many cases it is impossible to untangle cause from effect. In some cases it seems highly probable that domestic friction was the result rather than the cause of the alcoholic episodes. It is of interest that 122 patients (32.0 per cent) were unemployed. This was undoubtedly a contributing or precipitating factor in many cases.

Repressed homosexuality is considered by many to be the principal underlying cause of alcoholism. In this series 17 patients (4.4 per cent) admitted overt homosexuality, but this group included only 1 woman out of a total of 61. In 18 patients (4.7 per cent) there were hallucinations of homosexual abuse. In 48 patients (12.8 per cent), as stated above, there were delusions and hallucinations of being chased by gangs or police. It may be argued that the character of these delusions and hallucinations points, to latent homosexuality, but this seems to place an interpretation on the clinical material which is not warranted under the circumstances. There are undoubtedly many factors which either contribute to or are directly responsible for alcoholic excess.

#### SUMMARY

The number of alcoholic patients admitted to the Boston Psychopathic Hospital in 1937 almost doubled as compared with those admitted in 1927. This increase was not present among the groups with syphilis, manic-depressive psychoses and dementia praecox. It is not evident why the proportion of

As would be expected from the large proportion of Irish in Boston, the Irish alcoholic patients far outnumber all other nationalities. In 1937 there were 190 alcoholic patients of Irish extraction, or approximately half the total alcoholic admissions. The English numbered 58 (15 per cent). Thirty-eight (10 per cent) were of mixed race, while the remainder of the admissions were made up of widely scattered racial groups.

Most of the patients were between thirty and fifty years of age. Three were twenty or younger,

Table 2 *Admissions by Months*

January	29	July	34
February	24	August	33
March	29	September	40
April	29	October	33
May	32	November	23
June	39	December	36

56 were between twenty-one and thirty, 116 between thirty-one and forty, 148 between forty-one and fifty, 52 between fifty-one and sixty, and 7 were sixty-one or older. The youngest was sixteen and the oldest seventy-one.

As to schooling, 197 patients had not gone beyond the eighth grade, 156 had completed high school and 29 college.

Of the 382 patients, 83 (21.7 per cent) were sent to the hospital on a court order under a specific charge. Only 44 patients (14.0 per cent) were committed to other state hospitals, indicating that the majority of alcoholic psychoses cleared within the prescribed ten-day observation period.

Interesting information is to be obtained from a study of the physical and mental status of the various patients. There were 5 deaths (1.3 per cent), 2 in the delirium tremens group and 3 in the group designated as "alcoholic psychoses, other types." Two deaths were attributed to pneumonia, 1 to poisoning by bichloride of mer-

Table 3 *Varieties of Physical Disorder*

Ulcer of the stomach	1

cury, 1 to cardiac decompensation accompanied by uremia and peripheral neuritis and 1 to circulatory collapse with delirium and exhaustion. Table 3 indicates the number of alcoholic patients with evidence of physical disorder of a specific type. It is evident that neuritis, hepatic disorder

(including cirrhosis) and bronchitis far outnumbered other complicating diseases. We ordinarily associate neuritis and hepatic disorder with excess intake of alcohol, and although these disorders were present in 14.0 and 13.0 per cent of all alcoholic admissions, respectively, it is surprising that some clinical evidence of these disturbances was not found in even more cases. Bronchitis was relatively frequent, while pneumonia was an uncommon complication. Only 2 patients died of pneumonia, while 3 recovered. This is to be considered fortunate, since, as is well known, alcoholic patients succumb to pneumonia much more readily than do non-alcoholic ones. Serological tests for syphilis were positive in 14 cases (3.4 per cent). The total admissions of patients with syphilis made up 8.4 per cent of the total hospital admissions for 1937, or more than double the proportion in the alcoholic group.

Eleven patients showed evidence of lesions in the midbrain or medulla, with cranial-nerve palsies, which in some cases remained only for a brief period, while in others the neurologic findings persisted. Alcoholic patients having cranial nerve palsies usually showed a mental syndrome consistent with the diagnosis of Korsakow's psychosis, or chronic deteriorative changes, with varying degrees of loss of memory and of behavior disorders. No pathologic material was available for study in this group, as there were no deaths. It seems reasonable to conclude, however, that in an alcoholic psychosis accompanied by cranial nerve palsies we were dealing with a pathologic process known as the superior poliomyelitis of Wernicke.

It is of interest that 10 patients had convulsive seizures, or what the alcoholic patient commonly refers to as "rum fits." These seemed to be definitely associated with excessive alcoholism, since they occurred only after heavy bouts of drinking. Although convulsions are a relatively uncommon complication of alcoholism, it is well to bear in mind that seizures do occur in this group without any demonstrable evidence of pathologic lesions that would explain the convulsion on some other basis.

Optic atrophy occurred in only 6 cases. It is difficult to say whether there was a direct causal relation between the alcohol and the atrophy. It is well known that methyl alcohol will produce such a change, and that it is seldom found in patients who drink ethyl alcohol. There was no way of ascertaining whether alcohol was primarily responsible for the optic atrophy or whether it was an incidental finding. The same thing was true of testicular atrophy, of which there were 4 cases. There were also 4 cases of alcoholic pel-

## DIAGNOSTIC TESTS

Diagnostic tests for early pregnancy have been sifted down to a clear acceptance of the Aschheim-Zondek (mouse) and Friedman (rabbit) tests as the most reliable. Either test, when done by reliable technicians, will give a positive reaction in 98 per cent of normal pregnancies,<sup>3</sup> and will give an equal ratio of negative reactions in patients who are not pregnant. No other test yet described, chemical or biological, approaches these two in accuracy. When, however, evidence is required in pathologic pregnancies as to the status of the fetus in utero, for example in estimating the prognosis for the child in threatened abortion, or in cases where intrauterine death of the fetus is suspected, these tests must be looked on with caution. For example, in a patient known to be pregnant who has shown some vaginal bleeding, a repeatedly negative test would indicate death of the entire ovum, both fetus and appendages, if, however, the test is positive it is so because of endocrine activity of the still functioning trophoblast or placenta, and this cannot be adduced as an indication that pregnancy will continue successfully. In hydatidiform mole, moreover, the test is characteristically strongly positive, and becomes so again even after clinically complete evacuation of the mole if chorion epithelioma ensues. Finally, in the case of suspected ectopic pregnancy, the test, though valuable as confirmatory evidence if positive, does not in any way rule out the diagnosis if negative, as early death and degeneration of the ovum is the rule in this condition.

In summary it may be said that while in normal pregnancies the Aschheim-Zondek and Friedman tests are of great diagnostic aid, especially before the clinical signs are unmistakable, in pathologic pregnancy the wise clinician will evaluate his test findings on the assumption that they indicate the presence or absence of functioning trophoblastic tissue, either in the uterus or elsewhere.

## METABOLISM AND NUTRITION DURING PREGNANCY

Much attention has been paid in the literature to the metabolic and nutritional aspects of pregnancy. The routine weight chart of the patient is quite as important a part of prenatal care as are the blood pressure and urinalyses. Evidence has been accumulated in increasing volume that attempts to control the weight of the fetus at birth by regulating the weight of the mother are only partially successful. On the other hand, excessive increase in maternal weight, especially during the last three months of gestation, often due to mild or even subclinical edema, is a valuable sign of the insidious onset of hypertension or albuminuria or both.<sup>4</sup>

Metabolism of minerals and vitamins has been the subject of numerous papers. The addition of iodine to the diet in the form of syrup of hydriodic acid, five drops every other day, is believed by some to be of value to the pregnant woman in the goiter areas of the country, by lessening the incidence of congenital goiter and cretinism in infants. Lugol's solution, given by rectum and subcutaneously, has been advocated in the treatment of certain cases of vomiting of early pregnancy in which an underlying hyperthyroidism may exist.

An adequate intake of calcium and phosphorus in the form of one quart of milk, a liberal helping of green, leafy vegetables and a serving of meat at one meal, with the addition to the diet of an egg per day, is ordinarily amply protective so far as the maternal supply of these elements essential to the fetus is concerned. During the early phases of pregnancy, when "physiologic" nausea is common, it may be impossible to induce the prospective mother to take a properly adequate diet. Fortunately, however, the fetal demands reach a peak during the last months of gestation, when dietary whims are much better controlled by advice and suggestion.

It is important at this point to consider vitamin D as the catalyzer of calcium and phosphorus metabolism. Since it is of scanty occurrence in most "natural" foods, many clinicians prescribe it in the form of cod-liver oil or viosterol in the routine diet of pregnant patients, in order to ensure an adequate supply of calcium and phosphorus both to the maternal teeth and to the fetal skeleton. It is claimed by some that the muscular cramps which are so common in pregnancy are relieved by viosterol or inorganic calcium or both. Since, however, no convincing evidence has yet been adduced either that the maternal dental structure requires these supplements, or that the infant will fail to receive its normal skeletal requirements if these additions to the mother's diet are not made, and since premature ossification has been reported in fetus and placenta following large doses of vitamin D in pregnancy, the situation as summarized by Stander<sup>5</sup> is worthy of repetition: "Should it be necessary, because of dietary deficiencies, inability to drink milk, or lack of sunshine, to supply compounds of calcium and phosphorus, and vitamin D, these must be administered with care, certainly in respect to vitamin D, as overtreatment may be as injurious as the deficiency itself."

There is very little belief at present that even in toxemic pregnancy the diet should be low in protein, in fact, a small group of toxemic patients with the nephrotic syndrome should have a liberal protein intake. To place a pregnant patient

patients having syphilis among the alcoholic group was notably less than that among admissions in general

The most frequent complications were neuritis, hepatic disorders and bronchitis, pneumonia rarely occurred. There were only 5 deaths (1.3 per cent). It is not readily explainable why more patients did not have neuritis or pellagra, as the diet was deficient in more cases than showed these disorders, and this fact seems to point to a marked individual variation of reaction to similar precipitating factors. Patients showing cranial nerve palsies invariably showed gross intellectual impairment, indicating extensive involvement of the higher brain centers.

Twenty-two per cent of the patients had been

admitted on previous occasions. Approximately the same number of patients in this series had had previous alcoholic psychoses without hospital admission. There was no correlation between the type of hallucination and the duration of the psychosis. The most frequently occurring visual hallucinations were those of dogs and insects. Lilliputian hallucinations and occupational delirium were unusually rare. The number of depressed and suicidal patients in this series is noteworthy and deserves a more thorough investigation. Homosexuality, either overt or latent, was discovered in surprisingly few patients.

The etiologic and precipitating factors of alcoholic excess are most complex, and it seems that no single explanation will fit all cases.

## REPORT ON MEDICAL PROGRESS

### MEDICAL ASPECTS OF OBSTETRICS

THOMAS R. GOETHALS, M.D.\*

BOSTON

THIS article presents a sabbatical survey (since 1932) of progress in those aspects of practical obstetrics which may fairly be denominated medical rather than surgical, and leaves for a complementary review those aspects of the specialty which are of importance from the surgical standpoint. Since editorial policy calls for information of the broader aspects of progress, tempered with critical comment, rather than for a meticulous review of current literature, the writer has avoided, so far as possible, quotations of chapter and verse in favor of a concentrated summary of various important subjects.

#### PHYSIOLOGY

From a practical aspect, rhythm as a means of promoting or inhibiting pregnancy can undoubtedly be used successfully by many couples for long periods. Several authors both in Europe and in America have published clinical tabulations of many thousands of copulations during the "safe" period with complete avoidance of undesired pregnancies. These figures, however, convincing so far as they go, do not answer the logical objections that the human race is not yet sufficiently disciplined to regulate its emotional urges by the calendar, that variations in the time of ovulation in the cycle may occur, as evidenced by unpre-

dictable prolongations of the estrin or corpus luteum phases, and that the possibility of induced coital ovulation as an unorthodox occurrence in human biology cannot be entirely disregarded<sup>1</sup>.

Sex regulation of human offspring seems, by analogy with animal genetics, to be linked with the sperm cell which fertilizes the ovum. A theory that relative alkalinity of the vagina at the time of intercourse results in a preponderance of male children has been advanced, suggesting the use of sodium bicarbonate by douching or instillation before coitus if the birth of a boy is desired. This theory, advanced in the German literature before the rise to power of the present chancellor, has subsequently, and possibly to the disappointment of *Der Fuhrer*, remained unsupported by other investigators.

Prediction of sex in the unborn child has been attempted by various biological methods. Most attention has been paid to acceleration of spermatogenesis in the testicles of three month-old rabbits following the injection into the test animal of urine from women in the second half of pregnancy<sup>2</sup>. Though the original investigators of the test reported successful prediction of sex of the child in 80 of 85 cases, later investigators were unable to obtain confirming results.

The two preceding paragraphs indicate that no reliable method has yet been devised either to regulate or predict the sex of the human infant.

\*Assistant professor of obstetrics, Harvard Medical School; assistant visiting obstetrician, Boston Lying-in Hospital.

treatment of intercurrent infections and a close watch for the development of toxemic conditions. If this ideal is to be attained, each case should be followed by the internist and obstetrician, working in conjunction. Contrary to the theory that the pancreas of the fetus helps the maternal metabolism, experience seems to indicate that, in many cases at least, the diabetes becomes more severe during pregnancy, and requires a higher dosage of insulin for its control as pregnancy advances. The occurrence of hyperemesis in the first trimester may make control of the disease impossible, while during the last trimester, toxemia and eclampsia seem to be more frequent than in non-diabetic pregnancies. Despite improvement in the maternal risk, the fetal wastage is still higher than one would like to see it. Whether or not in the long run better fetal results will be obtained by routine abdominal section as soon as the infant is deemed viable,<sup>13 14</sup> or by reserving section only for over-large babies and ordinary obstetrical indications,<sup>15</sup> is still a controversial question.

#### PREGNANCY ASSOCIATED WITH CARDIAC DISEASE

It has been taught for many years on clinical grounds that the gravid state throws an extra burden on the circulatory system. Quantitative evidence obtained in the laboratory which has tended to rationalize this view is gradually being confirmed by observations made on living pregnant and parturient women. Thus, considering the finding that cardiac output rises to 50 per cent above the normal volume with advancing pregnancy, the finding that total blood and plasma volumes in the circulatory system also increase, and the frequency of rises in the systemic blood-pressure and pulse rate as gestation advances, no matter to what extent these processes are mutually causative, the increased burden on the circulation is evident.

That normal hearts and blood vessels adapt themselves to this strain is remarkable. That the damaged heart of the cardiac patient can bear this burden is often in doubt. The mere diagnosis of valvular heart disease does not give definite evidence of the organ's incapacity to withstand pregnancy, as many women with mitral stenosis or aortic regurgitation or a combination of the two may go through pregnancy and labor without any untoward event, some, on the other hand, have cardiac failure. Functional tests such as dumb-bell swinging, stair-climbing, and so forth, may reveal imminence of cardiac decompensation, but may give false assurance that the Class 1\* patient can reasonably be expected to stand the burden of

advancing pregnancy. It seems much more logical to believe with Hamilton<sup>16</sup> that the patient with a diastolic murmur, an unmistakable enlargement of the heart or both should be classed as an unqualifiedly bad risk for pregnancy if she has signs or history of decompensation, or if she has in addition auricular fibrillation, and to look upon her as a *relatively* favorable risk if fibrillation or signs or history of decompensation are absent, not, however, losing sight of the possibility that either of these conditions may arise despite strict medical supervision. A favorable cardiac case, classified on this basis, should have a 2 per cent mortality risk, an unfavorable case has been shown to have a 16 per cent risk, whereas one with auricular fibrillation courts a 33 per cent mortality.

Clinical evidence has accumulated that the peak load for the cardiac patient occurs toward the end of the sixth, during the seventh and at the beginning of the eighth month of pregnancy. Should the eighth month be passed without failure, the chances of decompensation during the ninth month or during delivery appear to be relatively small. Evidence has been adduced that the cardiac patient has neither a shorter and easier nor a longer and harder labor than the woman with a normal heart. The present trend is distinctly in preference of delivering favorable cardiacs through the pelvis at term, and of reserving abdominal section for those cases in which a purely obstetric indication exists.

The unfavorable cardiac, on the other hand, requires a different approach. She should, if contemplating pregnancy, be warned of the risk involved. If in early pregnancy, she should be allowed the option of abdominal abortion and sterilization. If, as often happens, she has started pregnancy as a favorable risk but later, because of decompensation, becomes unfavorable, the immediate treatment should be hospitalization, complete bed rest and intensive efforts to restore compensation. This regime, sometimes unavailing, is at best time-consuming, but often tides women over the seventh and eighth months, following which, with the peak load diminishing, the restored compensation allows a surprising proportion of these cases to be delivered safely through the pelvis.

In summary, it seems that the chief advances in the management of pregnancy complicating heart disease during the past seven years are largely the results of accurate classification of patients with seriously damaged hearts, the prognosis, according to classification, of the risks inherent in pregnancy and labor, and the relegation of abdominal section to a minor role in the obstetrical management of the favorable cardiac.

\*New York Heart Association and American Heart Association classifications.

on a meat-free diet is to invite the development of hypochromic anemia, and in certain cases to reduce the plasma proteins to an edema level. The ingestion of table salt, however, is a different matter, since an oversupply of the sodium ion, whether in the form of sodium chloride or of sodium bicarbonate, as taken immoderately by many women to combat flatulence and heartburn, tends to bind fluids in the tissues, thereby producing edema in the last trimester of pregnancy, when the ability of the kidney to excrete a highly concentrated urine is distinctly below normal.

The problem of vitamin adequacy in the diet of the pregnant woman has been widely discussed, and is still a somewhat controversial subject. For practical purposes a diet which contains milk, fruits and green and yellow vegetables each day and liver once or twice a week should be adequate for vitamin A, whole-wheat bread and whole-grain cereals will supply vitamin B<sub>1</sub>, liver, buttermilk and lean meat are good sources of vitamin B<sub>2</sub>, adequacy in vitamin C is assured by the daily ingestion of 6 to 8 ounces of orange juice, grapefruit juice or tomato juice. Vitamin D has been discussed above. Vitamin E is supplied by lettuce and wheat germ. Inadequacy of this substance has been claimed to result in abortion in the early months of pregnancy<sup>7</sup> and ablation of placenta in the last trimester,<sup>8</sup> and its routine administration in the form of wheat-germ oil has been advocated as a prophylactic against these conditions. The routine use of the substance, however, must be accepted with reservations, as the dosage is still empirical and the effects of overdosage are little if at all understood.

The hemoglobin content of the blood in pregnancy, especially in its latter half, is usually below normal. While this is undoubtedly due in part to the demonstrated increase in plasma volume which takes place at this time, it is nevertheless a fact that an actual anemia often occurs. This anemia has been postulated as due either to a direct dietary deficiency or to one conditioned by gastric anacidity, hypoacidity or associated defects, in the presence of fetal demand for blood-building material.<sup>9</sup> Microcytic (hypochromic) and macrocytic (hyperchromic) types have been described, the former occurring much more frequently than the latter. Ferrous sulfate, 9 to 12 gr daily, added to the diet is sufficient to combat hypochromic anemia, while liver or liver extract, with or without the addition of iron, controls the macrocytic or Addisonian-like type.

#### HYPEREMESIS GRAVIDARUM

While the etiology of hyperemesis gravidarum remains obscure, several points in the diagnosis

and treatment deserve comment. Toxic neuritis or neuronitis as a concomitant of prolonged or severe cases has been described, with a mortality of about 25 per cent in this group. Attention has been directed to the administration of vitamin B<sub>1</sub><sup>10</sup> by duodenal tube or parenterally, both prophylactically and therapeutically, in severe cases. Supra-renal cortex has also been advocated, but the original results on which this recommendation was based have not been repeated uniformly elsewhere. The administration of Lugol's solution by rectum or by the hypodermic route has been mentioned above. The procedure, however, of feeding fluids, calories and accessory vitamin factors B<sub>1</sub>, B<sub>2</sub> and C by duodenal tube has proved to have great value in severe cases, provided always that strict isolation of the patient from relatives and friends, preferably in a hospital, is observed.<sup>11</sup>

#### PREGNANCY ASSOCIATED WITH PULMONARY TUBERCULOSIS

Opinions still differ, as always, regarding the relative advisability of interrupting pregnancy in the tuberculous woman and of allowing the gestation to proceed to term. The general trend of thought is toward allowing the tuberculous gravida to continue in pregnancy, provided she has sanitarium observation and care or its equivalent, this is tantamount to ruling that the case be studied and cared for by the expert in tuberculosis, working in co-operation with the obstetrician. Pneumothorax in pregnant women is quite as feasible, if properly done, as in non-pregnant women, and recourse to this measure may enable many patients to go safely through pregnancy who could not otherwise do so. Floyd<sup>12</sup> seems to strike a sane middle ground in the management of the associated conditions when he advises the following measures:

For the case with healed or obsolete lesions, continuance in pregnancy under sanitarium precautions in the home.

For the case with early active lesions, the same with pneumothorax.

For the case with well-established tuberculosis, pneumothorax at once, otherwise therapeutic abortion.

For the advanced case with a poor prognosis from tuberculous standpoint, continuance in pregnancy for the benefit of the infant.

For the case with military infection, neither pneumothorax nor abortion, as neither procedure improves the prognosis.

#### PREGNANCY ASSOCIATED WITH DIABETES MELLITUS

Because of the control of diabetes by insulin, more diabetic women are able to conceive and bear children than was ever possible in the pre-insulin era. The essential factors in the successful management of such cases are close control of the diabetes by means of diet and insulin, the skillful

## PUERPERAL INFECTION

Certain important elements in the prophylaxis and treatment of puerperal septic infections deserve consideration

There has in the past few years been a marked stimulus to the obstetric conscience in the realization that the original focus of many cases of intrapartum as well as postpartum infection lies in the nasopharynx of an attendant. The idea is not new, and it has been frequently stressed since it was called to the attention of the profession in a clearly written article by Watson and his associates<sup>20</sup> in 1928. The presence of infectious organisms in the noses and throats of physicians, nurses and other hospital attendants is quite as common as in the population at large, and their insidiousness lies in the fact that no clinical symptoms may be present in the host. In other words, *everyone is a potential carrier*. As an obvious corollary, every person in attendance on a woman at delivery, and every nurse performing the perineal toilet of a postpartum patient, should, in addition to scrupulous care in digital asepsis, be effectively masked as to nose and mouth. In addition, every person known to be a carrier of the hemolytic streptococcus should be rigidly excluded from delivery or nursing care of the obstetric patient until such time as absence of the organisms is assured.<sup>21</sup>

The therapy of puerperal infection has been greatly advanced by the work of Colebrook and his associates in England, and by Long, Keefer and others in this country. The first-named group,<sup>22</sup> using Prontosil by oral, intramuscular and intravenous routes in 64 puerperal cases of infection with beta hemolytic streptococci, and later administering the allied substance sulfanilamide, usually by the oral route alone, to 100 other cases, were able to report a reduction in mortality in streptococcal infection from 23 per cent in the preceding five years to 5 per cent since early 1936. Keefer<sup>23</sup> reports that sulfanilamide used in treatment of puerperal sepsis due to streptococci prevents the local process from spreading, and inhibits invasion of the blood stream. In his experience in cases with bacteremia, with or without peritonitis or extensive thrombophlebitis, mortality has been reduced from 70 to 40 per cent.

A formidable amount of literature dealing with the effect of sulfanilamide on all types of streptococcal infections has appeared. Evidence indicates that the drug is bacteriostatic rather than bacteriocidal or antitoxic, and that its best effects are obtained in those cases which have some power of mobilizing an immune reaction against the invading organism.

Despite the fact that sulfanilamide provides

us with a potent therapeutic measure against the most dreaded agent of puerperal infection, a word or two of caution should be mentioned. Not all forms of sepsis are benefited; the drug is most active against the beta hemolytic streptococcus, but certain strains of this organism are resistant to its action, against the staphylococcus it has relatively little effect. Sulfanilamide therapy, to be effective, requires heavy dosage of the drug, with control determinations of the percentage level of the substance in the blood stream. Malaise and cyanosis are almost universal. The hemoglobin and red- and white-blood-cell counts should be determined at least every two days or better every day, because mild hemolytic anemia is common, and acute hemolytic anemia and agranulocytosis occur occasionally, as toxic manifestations. A fever due to the drug itself occurs in 9 per cent of the cases, according to Long,<sup>24</sup> and is an urgent indication for omission of the therapy.

It seems fair to conclude that the use of sulfanilamide in puerperal infection is an effective, though somewhat two-edged, measure. The physician prescribing it will be well advised to draw no conclusions concerning his results unless they are bacteriologically controlled, and unless they are obtained under the most scrupulous clinical observation, aided by adequate laboratory investigation.

# HYPERTENSION AND ALBUMINURIA, EXCLUSIVE OF ECLAMPSIA

A survey of seven years reveals little if any progress in the discovery of a single background which suffices to explain the occurrence of these toxemic conditions. Claims have been made that a vicious cycle may be started in the second half of pregnancy by an oversupply of fluids to an individual whose renal capacity for water excretion is physiologically depressed, and that this cycle may proceed to a generalized edema which, acting on the central nervous system, may result in eclamptic convulsions and coma. The work of certain investigators pointing toward an etiology based upon increased activity of the posterior pituitary, through which they explain edema and oliguria by antidiuretic action of the hormone, and hypertension as the result of the pressor action of the same secretion, has not been confirmed by others. Retention of sodium ion resulting from an oversupply of sodium salts or from the inability of the kidney to excrete a concentrated urine has had its advocates as an important etiologic factor. Another endocrine background has been noted by investigators who find excessive amounts of prolactin in the blood, urine and placenta of toxemic patients, with a tendency toward a depression of the estrin level from the same sources. A recognized or unrecognized pre-existing pyelitis or pyelonephritis, it has been claimed, sets the stage for the subsequent development of toxemia during pregnancy. Finally, changes in the placenta, with infarction of this organ resulting in the elaboration of protein split products, such as guanidine, are looked upon by some as the causative factor. Strangely enough, very little is said concerning the ancient bugbear of nitrogen retention resulting from a diet supposedly too rich in protein.

From the standpoint of classification some progress has been made. Certain patients showing evidence of disease independent of pregnancy may be identified as having vascular hypertension, nephrosis or nephritis. Most cases, however, as first seen during pregnancy, give no history and yield no evidence of disease, so far as the physician can learn at first glance, independent of the pregnant state. These are divided into two categories: low-reserve kidney, according to the classification<sup>17</sup> of the Johns Hopkins Hospital, or pre-eclampsia, Grade 1, by the standards of the Boston Lying-in Hospital,<sup>18</sup> and pre-eclampsia (Johns Hopkins Hospital) or pre-eclampsia, Grade 2 (Boston Lying-in Hospital). The dividing line between the two is more or less arbitrary, and consists in the degree of hypertension or albuminuria or both, prodromal symptoms and signs suggest-

ing impending eclampsia are limited to the second group.

Despite the admitted uncertainty of the etiology of the toxemias of late pregnancy, and the numerous recently published studies of blood chemistry and renal function, certain basically important measures in the treatment of these conditions may be stated as within the scope of any physician who practices obstetrics.

Constant control of the pregnant patient by watchful interpretation of her symptoms and changes in her blood pressure, urine and weight.

Increased surveillance, even to hospitalization, should hypertension, albuminuria or both appear.

Salt poor or salt free diet, restriction of fluids by mouth, bed rest, moderate saline catharsis and strict watch for rising blood pressure or increasing albuminuria after the above signs appear.

Interruption of pregnancy should hypertension be unchecked, albuminuria increase or nervous symptoms suggesting impending convulsions appear after the above regime is instituted.

## ECLAMPSIA

This condition remains a "disease of theories." Both in its temporal relation to pre-eclampsia (Grade 2) and in its blood picture it is undoubtedly more closely allied to the latter condition than to nephritis, even though it often leaves impaired kidney function as a sequela after pregnancy has terminated. Closely allied though pre-eclampsia and eclampsia may be, it is important to recognize that the pre-eclamptic patient who becomes eclamptic exchanges a 25 per cent risk of death for one of 25 per cent,<sup>18</sup> hence the dictum that eclampsia is better prevented than cured.

Recent experience convinces us of several points in the treatment of this condition.<sup>19</sup>

Broadly speaking, the essence of a successful result lies in conservative treatment aimed at controlling the convulsions.

Conversely, immediate delivery by any means, above all by abdominal section (save in the rarest individual case), should be strongly deprecated.

Hospitalization and special nursing, if available, provide an environment more favorable than the home.

Morphine as a medication for control of convulsions may be better replaced by barbiturates administered by mouth or, in comatose patients, by rectum or intravenously, as an immediate or emergency measure.

Magnesium sulfate given intravenously, 20 cc. of a 10 per cent solution, will control the convulsion, and repetition of this dose to the extent of 60 to 80 cc. in twenty-four hours may be safely carried out if repeated convulsions occur or impend.

Frequent examinations or colonic lavage may excite further convulsions.

Hypertonic glucose solution given intravenously is advantageous in combating oliguria and anuria.

If labor ensues following convulsions, Nature has been kind. If the convulsions have been well controlled, induction of labor by rupture of the membranes is advisable.

showed marked weakness, slight cyanosis, nausea and vomiting. The vomitus gave a 3+ guaiac test. His blood pressure was 110 systolic, 90 diastolic. Moist rales were heard at both lung bases. Following a transfusion the patient seemed slightly improved, but the following day was weaker than ever. On the fourteenth hospital day respirations were shallow, the pulse weak and thready, the blood pressure 80 systolic, 50 diastolic, and the temperature 96°F. His condition rapidly became worse, his pulse and blood pressure were unobtainable, the fingertips became cyanotic, and respirations were labored. An oxygen tent, intravenous dextrose and other stimulants had little effect, and the patient died that afternoon.

#### DIFFERENTIAL DIAGNOSIS

DR. BERNARD M. JACOBSON. I do not believe that we can consider the generalized edema and ascites as due to heart failure on the basis of arteriosclerotic heart disease with congestive failure. He had no symptoms suggesting such a diagnosis and no physical signs referable to the heart. The question might be raised whether we could consider this nutritional edema either dependent on protein deficiency over a long period of time or due to a beriberi type of heart failure with generalized edema. Against these two rare possibilities is the fact that he is reported to be well nourished. Apparently he ate well during the month before admission, and there was no alcoholic history, polyneuritis or massive amount of protein in the urine. On the other hand, it seems to me that we have most of the evidence needed for a diagnosis of primary renal disease. We have a story of previous nocturia over a period of six to eight months and of generalized edema reinforced by a gain of 10 pounds in weight, in spite of not being up to par before entry. The principal findings consisted of generalized edema, marked ascites and possibly fluid in the pleural cavities. The laboratory findings were also consistent—a high specific gravity and massive amounts of albumin and many casts in the urine. The serum protein was low, and the serum cholesterol high, 317 mg. The rather low value for the serum chlorides, 85 milliequivalents, is not the rule in chronic parenchymatous nephritis with edema, but it does occur. We are not told whether the plasma bicarbonate was determined. We should expect it to be high if the chlorides were really low. Of course the chloride deficit in the blood might well depend on previous vomiting and poor chloride intake. The determination, however, was apparently not repeated.

On the day after admission two midline paracenteses failed to evacuate any fluid except a few blood tinged drops which might have come from

the edematous abdominal wall." I do not know how to explain that in view of the very definite physical findings of ascites.

"That night the right leg and arm suddenly became numb, the fingers of the right hand crossed and could not be moved, and he was unable to move his arm or leg." A very curious symptom which is not mentioned later in the record, so I assume that it disappeared in the course of a short time. It suggests carpopedal spasm, possibly due to some form of tetany. Was the tetany due to a calcium deficit in the blood? I do not believe so. It is not very usual to see so low an amount of ionized calcium in a person with marked renal disease. Could it have been due to high plasma-bicarbonate accompanying low blood chlorides? It is possible. I doubt whether it was a cerebral vascular accident because it cleared so rapidly.

We get no further information about the progress of the erythematous area on the right lower abdominal wall. One wonders whether it could have been erysipelas or an erysipeloid infection. One speculates as to whether there was a phlebitis. Since it is not mentioned again, I do not believe it warrants further consideration. With all these symptoms and physical signs, I do not see how we can get away from terminal cardiac failure, but I have already mentioned reasons why heart failure cannot be considered as the primary cause. Everything points to chronic renal disease as the background of the entire picture.

Of the types of renal disease this might be, certainly the commonest is chronic glomerulonephritis with edema—the nephrotic stage of chronic glomerulonephritis. It is rare to see such a marked number of casts in urine from a case of amyloid disease of the kidney. We have no history to suggest amyloid disease, and the only cases of idiopathic amyloid disease I have ever seen have had very definite signs of infiltration of the liver and spleen as well.

Is this myeloma involving the kidney, in view of the fact that the urine was examined for Bence-Jones protein? It seems unlikely. Is this acute glomerulonephritis? I doubt it. Against it is the lack of hypertension, the lack of very much sediment in the urine or very many red blood cells and the lack of a marked degree of nitrogenous retention in the blood. My diagnosis is chronic glomerulonephritis, with edema and terminal congestive heart failure.

DR. FRANCIS T. HUNTER. When I saw this man, very little laboratory work had been reported. He had a blood nonprotein nitrogen which was not very high—40 mg per cent—and had had three urine examinations. The lowest gravity of the

## CASE 25051

### PRESENTATION OF CASE

A fifty-four-year-old married insurance agent entered complaining of abdominal swelling of two weeks' duration.

He was perfectly well until six or eight months before entry when he first noted weakness and lack of force in his urinary stream. There had been no dribbling or difficulty in starting or stopping the flow. Since then he had nocturia once each night. One month before entry he noticed swelling of his left leg which came on during the day and subsided at night. During the following week the edema gradually became generalized, involving the face and hands. Enlargement of the abdomen developed two weeks before entry. This gradually increased, causing respiratory embarrassment and a sensation of fullness in the chest. He had had chest pain, alternating from side to side on inspiration, without other symptoms during the previous winter, but had had no dyspnea or edema at any time before the onset of the present illness. No cough, sputum, anginal pains or palpitation had been noted. His urine had become somewhat hazy but there was no change in color. During the past two weeks he had been confined to bed and fed only liquid food. His appetite was good, and he had had no previous nausea, vomiting, malaise, chills or fever. His bowel movements had been regular and of normal color. After being confined to bed, however, he had had nausea and vomiting on two consecutive nights. The vomitus contained no trace of blood or bile. He had gained 10 pounds in weight. His past and family histories were noncontributory. He had had his gall bladder removed twenty-three years previously.

Physical examination showed a well-developed and nourished man having some difficulty in breathing. Pitting edema was present over the entire body. The tongue was coated. The diaphragms were high on both sides, but examination of the lungs was negative. The heart was not remarkable. The blood pressure was 130 systolic, 84 diastolic. There was marked abdominal distention, and tympanites with shifting dullness in the flanks. No tenderness was present,

and no masses could be palpated. There was an old cholecystectomy scar in the right upper quadrant.

The temperature was 97.8°F., the pulse 90, the respirations 20.

The urine was amber colored and acid in reaction, with a specific gravity of 1.034, a large trace of albumin, many hyaline casts and an occasional red cell and 3 to 5 white cells per high power field. The blood showed a red-cell count of 4,970,000, 90 per cent hemoglobin, and a white cell count of 15,500 with 90 per cent polymorphonuclears. The serum nonprotein nitrogen was 40 mg per cent, the protein 4.5 gm. The chlorides were equivalent to 85 cc N/10 sodium chloride. A blood Hinton test was negative.

X-ray films showed a large abdomen containing fluid. The right kidney outline was visible and not definitely abnormal, the left was not seen. The gas shadows in the bowel were not abnormal. There was no evidence of abdominal tumor. The diaphragm was high on both sides, particularly on the right. An area of density, apparently fluid, partially obscured the outline of the diaphragm and obliterated the right costophrenic angle. The left lung was clear. The heart and mediastinum were not remarkable.

On the day after admission two midline paracenteses failed to evacuate any fluid except a few blood-tinged drops which might have come from the edematous abdominal wall. That night the right leg and arm suddenly became numb, the fingers of the right hand crossed and could not be moved, and he was unable to move his arm or leg. He had fleeting pains in the left chest. These symptoms passed away within a few minutes, and he was again normal. On the fourth day his edema had increased and involved the right leg more than the left. Erythema appeared on the right leg and lower abdominal wall. The skin of these areas was very sensitive. Salyrgan and ammonium chloride therapy caused no diuresis. On the seventh day digitalization was begun. The urine showed no Bence-Jones protein. The serum nonprotein nitrogen was 40 mg per cent, and the cholesterol 317 mg. An electrocardiogram the following day showed a P-R interval of 0.2 seconds. There was no evidence of myocardial damage. Urine examinations during the next three days all showed a specific gravity of 1.016, a trace to a large trace of albumin and a rare red blood cell and 2 to 3 white blood cells per high power field. One specimen showed many finely granular casts. A stool was guaiac negative. The blood white-cell count was 11,100. On the eleventh day the serum protein was 4.4 gm per cent. The following day the patient

is excreted through the kidneys. In the course of that process it apparently causes a considerable amount of irritation, and a large amount of hemoglobin is precipitated in the kidney tubules in the form of casts. These are so numerous that the hypothesis has been made that death is due to an intrarenal hydronephrosis—a complete blocking of the tubules with precipitated hemoglobin. I do not think that has been clearly proved, but on occasions the appearance of the kidneys suggests it.

DR. ALLEN G. BRAILEY: Should he not have had ascites?

DR. MALLORY: It is extraordinary that he did not have it.

DR. HUNTER: Did we not have a patient eight or nine years ago in his sixties with a lipoid nephrosis?

DR. MALLORY: Yes.

DR. HUNTER: But this is not lipoid?

DR. MALLORY: No, but the symptomatology is identical. There is no way to hypothesize clinically whether the tubular degeneration is going to be of the albuminoid type or of the lipoid type.

DR. HUNTER: The interesting thing about the urinary output was that the highest was 1500 cc., when he came in, with more or less tendency downward, and he was finally putting out about 900 cc., a little more than he was taking in.

DR. MALLORY: A very high specific gravity is characteristic of the disease.

DR. PALMER: Particularly because of the albumin?

DR. MALLORY: Yes.

## CASE 25052

### PRESENTATION OF CASE

A fifty-seven-year-old native housewife was admitted complaining of vaginal bleeding.

She had been perfectly well, and her menses had been normal and regular until ten years before admission, at which time she had an unruptured appendix removed. The right ovary and tube were removed at the same time because, she was told, of 'adhesions.' Fourteen days after the operation she developed an incisional hernia. However, she had complete amenorrhea until ten months before entry when spotting with bright red blood began. Six weeks after this bleeding started she entered an outside hospital, where a left ovarian cyst and part of the ovary were removed. The pathological report was papillary cystadenoma, without evidence of carcinoma. She was discharged well in fourteen days. About a month later she began bleeding again and a series of twelve x-ray treatments was given. After another month the

bleeding resumed and continued until entry. She had had no cramps, pain or weakness, though she had had occasional "dizzy and weak spells." She had lost 25 pounds in weight, from 200 to 175, during the year before entry. There were no gastrointestinal or urinary symptoms. She had had two children.

Physical examination showed an obese female in no distress. Examination of the lungs was negative. The heart was slightly enlarged to the left, and there was a rough apical systolic murmur. The sounds were regular and of good quality. The blood pressure was 205 systolic, 105 diastolic. The abdomen showed right rectus and left paramedian scars. On the right was a large incisional hernia. Vaginal examination showed a slightly enlarged uterus, there was profuse bleeding from the os. The uterus was movable. Nothing further was discovered by rectal examination.

The temperature, pulse and respirations were normal.

The urine examination showed a slight trace of albumin and 35 red cells and 20 white cells per high-power field. The blood showed a red-cell count of 2,700,000 with 55 per cent hemoglobin, and a white-cell count of 5700 with 61 per cent polymorphonuclears. The platelets were normal.

On the second hospital day an operation was performed.

### DIFFERENTIAL DIAGNOSIS

DR. LANGDON PARSONS: All this patient's trouble seems to date from her first surgical experience ten years before. One wonders about the initial diagnosis of appendicitis. There is nothing to show whether the appendix was diseased, but at any rate we go on to find that the right ovary and tube were removed. Apparently the appendix was not regarded as the sole cause of her symptoms. Whether the lesions of the tube and ovary were due to pelvic inflammation or endometriosis or anything you will, it is surprising that the other tube and ovary were not involved and likewise removed. Then after amenorrhea of ten years' duration she began to bleed bright-red blood and again entered a hospital for operation. Laparotomy was apparently done without curettage so we have no knowledge of what was going on inside the uterus. Evidently a mass was felt and proved to be ovary. The surgeon removed an ovarian cyst but only part of the ovary. There is little excuse for not removing all ovarian tissue in a woman of fifty-seven when laparotomy is done. Nothing was done about the uterus, probably for the reason that she was obese and hypertensive and regarded as a poor risk. With bleeding past the menopause, you are practically committed to do-

urine was 1 016, and the highest 1 034. It certainly did look like a nephrotic picture, but as I recall, some years ago we had an individual just like this who was given digitalis because it would not do him harm, and promptly lost all his edema. The question was brought up whether he ought to be transfused, despite a red-cell count of 4,900,000. I think it was right to rule out any possibility of cardiac failure first because, if he had had it, transfusion would have been the worst thing that one could have done for him. Subsequently the electrocardiogram turned out to be negative, and it was rather obvious in a short time that the cardiac situation played no part in his picture.

DR RICHARD CLARK: What did his prostate feel like?

DR HUNTER: I doubt if one could tell on account of the edema. He had the most amazing legs I have ever seen. They were covered with big patches of erythema. It was more like a cellulitis, almost ready to burst. The edema was worse in the dependent part of the body than higher up.

DR ROBERT S. PALMER: If this is a nephrotic phase of a glomerulonephritis, what happened to the red area in the abdomen? Such cases often die of some intercurrent infection.

DR TRACY B. MALLORY: At the time of autopsy there were none present. Erythemas often disappear post mortem.

#### CLINICAL DIAGNOSES

Chronic nephritis, nephrotic stage  
Congestive heart failure

#### DR JACOBSON'S DIAGNOSES

Chronic glomerulonephritis, nephrotic stage  
Congestive heart failure

#### ANATOMICAL DIAGNOSES

Acute nephrosis, albuminoid type  
Acute pulmonary edema  
Peripheral edema

#### PATHOLOGICAL DISCUSSION

DR MALLORY: The autopsy showed this very generalized edema which had been noted. The principal reason the abdominal taps were negative was that the peritoneum did not contain any ascitic fluid. The abdominal wall was extremely edematous and made the abdomen seem swollen. The pleural cavities were also dry, although the lungs were quite edematous. The heart was normal in size, the coronary arteries and adrenals were negative. The myocardium was normal. The significant positive finding was a pair of very much enlarged kidneys, weighing

500 gm. They were reddish, rather than yellow, but rather pale. When the capsule was incised the parenchyma bulged out over the capsule indicating that the cortex was quite swollen—it measured about 9 to 10 mm in thickness. On microscopic examination the glomeruli showed surprisingly little. He was, after all, in his fifties, and perfectly normal glomeruli could hardly be expected. There was a trace, perhaps, of thickening of the capillary walls here and there, but I am sure no more than the average man of fifty would be apt to show. In an occasional glomerulus one could find a few more leukocytes than usual but they were not very numerous, I do not believe we found more than 10 in any glomerulus. Although I can imagine a great deal of difference of opinion between histopathologists, I should say the glomeruli were essentially negative. The tubules, in contrast, showed an extreme grade of degeneration. All the cells of the convoluted tubules were greatly swollen and the fuchsinophil granules were frequently swollen to nine or ten times the normal diameter. It is the so-called albuminoid degeneration that is very characteristically seen in nephrosis. To find this type of kidney disease in a five- or ten-year-old child would not surprise me very much, but I have never before seen it in a fifty-four year-old man. It comes as near to pure nephrosis as I have ever seen. I do not know why he died. He was obviously not uremic. He unquestionably had some degree of infection but did not have a positive blood culture. The head was negative.

DR HUNTER: Perhaps the transfusion was bad for him.

DR MALLORY: At any rate it was not a "transfusion" kidney.

DR JACOBSON: Was there any lipid?

DR MALLORY: Practically none whatever. There were very slight deposits in an occasional tubule but not in the tubules that showed the most marked swelling and degeneration.

A PHYSICIAN: Was the carbon-dioxide combining power of the blood determined?

DR HUNTER: No.

DR THORNTON SCOTT: Was the pulmonary edema sufficient to cause death? He seemed to die a respiratory death.

DR MALLORY: There was certainly a considerable grade of pulmonary edema. His lungs were heavy, weighing 1600 gm. On the other hand, with fatal pulmonary edema the weight usually goes up to 2000 gm or more.

DR RICHARD CHUTE: What do you mean by a "transfusion" kidney? What does it look like?

DR MALLORY: If a mismatched transfusion is given, hemolysis is produced and the hemoglobin

DR. PARSONS We have seen another case in a woman of forty where the two were associated

DR. MEIGS Have you seen the association with any frequency, Dr. Smith?

DR. SMITH We have had two cases with adenomyosis and carcinoma starting in the adenomyosis without endometrial involvement

DR. MEIGS You mean carcinoma in the wall of the endometrioma? I have never seen it

DR. MALLORY Here I think it is clear that the carcinoma started in the endometrium itself, not in one of the more distant spots of endometriosis. We did have one case here, I remember, where we found an adenocarcinoma in the serosa of the sigmoid with a perfectly normal mucosa and muscularis overlying it, and we raised the question whether it might not have been carcinoma starting in an endometrial implant

DR. MEIGS It is well known that you can have carcinoma in the ovary apparently developing from an endometrioma, but I have never happened to see it in the uterine wall. It certainly occurs in the ovarian wall and I should think you might find it in the wall of the sigmoid when an endometrioma is there. The unaccountable thing in this case is the fact that they gave x-ray treat-

ment without knowing what was wrong inside the uterus in a woman fifty-seven years of age

DR. MALLORY Your inclination would be to believe that there was cancer there at that time?

DR. MEIGS Yes, I should think so

DR. PARSONS Carcinomas of the fundus are slow-growing and do not take on marked activity unless they have invaded through the wall of the uterus or extended to the adnexa. A history of bleeding for a year is still consistent with carcinoma

DR. MALLORY It could certainly last a long period of time. I remember one case where we made a diagnosis of atypical polyp of the endometrium but, since we could not exclude cancer, advised very careful following of the patient. She was lost track of for five years, then came back, and at that time had definite cancer, but the lesion was still only 2 cm in diameter and had not invaded the myometrium

DR. PARSONS Dr. Meigs has a patient known to both of us who, when told she had carcinoma of the fundus for which surgery was advised, replied "That is interesting because I was told the same thing ten years ago and nothing was done"

ing a total hysterectomy unless you can prove that there is nothing inside the uterus

This is a controversial point and I do not know whether Dr Meigs and Dr Mallory will back me up, but it has been my impression that an ovarian carcinoma does not cause bleeding past the menopause unless it involves the fundus of the uterus by extension of the disease or unless it is a hormone-secreting type which produces hyperplasia of the endometrium from which bleeding occurs. If that is true, this patient was probably not bleeding because she had an ovarian cyst, and removing the cyst and part of the ovary would not be expected to end the bleeding. The original pathological specimen was reported as papillary cyst adenoma, without evidence of carcinoma. We know papillary cyst adenomas of the ovary are borderline tumors, and there may have been some portions of the tumor which were malignant, so it is conceivable that there was extension of the tumor to the uterus to account for the bleeding. However, we must go on the basis of the original pathological report, at least for the time being, and assume that it was a non-malignant tumor. If that is true, we still have not explained the bleeding. In spite of that fact, a month later x-ray treatment was given to stop the bleeding. It is my impression that x-ray treatment will not control uterine bleeding in the absence of ovarian function. In other words x-ray treatment was given without knowing why the bleeding occurred and, to my mind, with little likelihood of controlling it.

I believe the bleeding was due to a carcinoma of the fundus, as a second choice, portions of the papillary cyst adenoma might have been malignant and the bleeding may have resulted from extension of the disease to the uterine fundus.

DR JOE V MEIGS To my mind the whole operative procedure was wrong. To think that a benign papillary cyst adenoma in one ovary was responsible for abnormal bleeding in a woman of fifty-seven is false reasoning. On the other hand, after looking up the cancerous lesions of the ovary in our hospital I believe some patients bleed from the endometrium who do not have extension to or hyperplasia of the endometrium. I have argued about this with Dr Parsons for a long time. It is my impression that with certain types of ovarian tumors the endometrium may be active even though it does not show signs of hyperplasia. Some of these tumors secrete enough hormone to stimulate the endometrium, but I have also seen patients with malignancy of the ovary who bleed from apparently inactive endometrium. Why, I do not know. Hence, I do not believe it is necessary to have a metastasis or

hyperplasia or even an active endometrium.

X-ray treatment should not be given to a woman fifty-seven years of age in whom a positive diagnosis as to the cause of bleeding has not been made. No one in this hospital would do it without investigating the inside of the uterus, particularly since we do not approve of x-ray treatment for postmenopausal uterine bleeding.

DR GEORGE G SMITH I agree with what Dr Meigs has said. Our experience has certainly been that it is possible to have ovarian tumors of various types, including cancer, that are associated with uterine bleeding, mostly slight in character, for which no definite cause can be found, although in some instances there is a mild degree of endometrial activity.

Carcinoma of the fundus  
Extension of papillary adenocarcinoma of the ovary?

#### ANATOMICAL DIAGNOSES

Adenocarcinoma of the fundus of the uterus  
Endometriosis

#### PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY On this patient's entry into the hospital a curettage was performed preliminary to hysterectomy. From a frozen section the pathologist was unable to make a definite diagnosis, though he was suspicious of carcinoma. Since he could not exclude cancer a hysterectomy was urged. The uterus was removed with considerable difficulty because it broke in the operator's hands and he had to go back and remove the cervix secondarily. The uterus therefore arrived in the laboratory in two pieces, neither of which grossly showed any obvious tumor, but on microscopical examination it is quite clear that it contains two lesions which I have not happened to see associated before. There is a frank endometrial carcinoma, and there is also a very widespread endometriosis with a considerable number of foci deep in the wall of the uterus. In some fields it is almost impossible to decide whether one is looking at endometriosis or carcinoma or perhaps a mixture of the two. In fact among the islands of endometriosis that are clearly surrounded by endometrial stroma two types of glands may be found, one of which looks fairly normal whereas the cells lining the others have all the cytologic characteristics of malignancy.

DR. PARSONS We have seen another case in a woman of forty where the two were associated

DR. MEIGS Have you seen the association with any frequency, Dr. Smith?

DR. SMITH We have had two cases with adenomyosis and carcinoma starting in the adenomyosis without endometrial involvement

DR. MEIGS You mean carcinoma in the wall of the endometrioma? I have never seen it

1 each in Rhode Island, Massachusetts, Vermont and Maine,—the present case being the fifth in New England and the second in Massachusetts. It has been pointed out in a previous editorial\* that the advisability of importing Western rabbits for restocking the depleted native rabbit population is open to serious question. It is true that such a practice has apparently not resulted in the infection of native rabbits in states, such as Connecticut and New York, where restocking has been carried out for several years. This and the absence of the spontaneously occurring disease in native rabbits may be explained by a low incidence of insect vectors—ticks, lice and fleas—in most sections of the northeastern states. The climatological conditions on Cape Cod are quite different,—closely approaching those in states, such as Maryland, where tularemia is of common occurrence,—and it is not unreasonable to predict that the introduction of Western rabbits there may eventually lead to a sharply localized area where the disease in rabbits and human beings is prevalent.

The prevention of tularemia is largely a matter of personal precaution. Sick or dead wild rabbits should not be handled. Rubber gloves should be worn by those who dress them and other wild animals, but even then, sharp fragments of bone can pierce the glove and puncture the hand. Tick bites in an infested area are potentially dangerous. Rabbit meat should be thoroughly cooked. If subsequent cases of tularemia are reported from Cape Cod, instructions as to the symptoms and methods of prevention of the disease must be widely publicized.

#### POSTPARTUM HEMORRHAGE

Mrs. E. C., a twenty-four-year-old primipara at term, was admitted to the hospital on June 30,

1928, after the membranes had spontaneously ruptured. She was not in labor.

Her past history was essentially negative. Catamenia began at thirteen, were regular with a twenty-eight-day cycle, and lasted four days without pain. Her last period was October 1, 1927, making her expected date of confinement July 10.

She was first seen on May 8. Physical examination showed the heart not enlarged, and the sounds regular and of good quality. The lungs were clear and resonant, there were no rales. Her blood pressure was 124 systolic, 62 diastolic. The fundus was 27 cm. above the symphysis. Vaginal examination showed the cervix soft, the vertex presenting. Her pregnancy progressed normally until entry to the hospital.

On July 2, two days after the membranes had ruptured, she was given castor oil and quinine, which resulted in pains off and on during the day. At 10 p. m. the pains were coming every five minutes and she was given chloral and morphine, which quieted her down. On July 3 a rectal examination at 8 a. m. showed the head engaged and the cervix taken up and admitting one finger. At 2 p. m. the cervix admitted three fingers, but the pains were inconsequential. Soon after this she was etherized, and a vaginal examination made. The cervix was found to admit four fingers and was soft, the fetus was in an OLA position. A version was done without difficulty, and a male child weighing 6 pounds, 9 ounces, was delivered. A minor laceration was repaired routinely. The placenta was almost immediately expressed intact, with membranes complete.

Following the delivery of the placenta, there was a great deal of fresh blood and a large clot. The uterus remained contracted for about an hour and then relaxed. With each subsequent contraction there was considerable hemorrhage. Whereas at the end of the delivery her pulse was 100, it gradually rose to 130, her blood pressure went down to 60 systolic. She was somewhat pale and perspired freely. Oxytocics were given intramuscularly without benefit. (The use of intravenous injections of pituitary extract had at that time not become general.) Her blood was matched with that of her husband, and as he was compatible, she was transfused with 600 cc., followed by 400 cc. of saline. Her pulse came down to 110, her blood pressure rose to 98 systolic, and her general condition improved. The convalescence was uneventful, and she was discharged seventeen days following delivery.

*Comment.* This case occurred ten and a half years ago. At that time it was a common but not

## UNPRECEDENTED!

THE annual New Year boasts and boosts of days gone by have ceased to concern themselves with our economic fabrics, the hoarse prophets in the market places are strangely silent. We sneak from one year to another fearfully harkening to the professional agitators and devoutly hoping that the cataclysm may be postponed another twelvemonth.

In this issue, the *Journal* presents what must be construed as the effect of society's kaleidoscopic impacts upon the health of its individuals. Somehow the bodily changes of fear, pain, hunger and rage have girded us as never before against bacterial invasions—particularly those of the respiratory tract. The death rates for tuberculosis, pneumonia and influenza have never before been so low in the United States. We do not recall that the physiologists ever made it clear that these bodily

changes lead to the exercise of greater caution or prudence, but it now appears that eleven thousand fewer people were killed in accidents of all kinds (eight thousand of them having escaped deaths in automobile accidents) in the United States during 1938. Possibly this may follow the lowered sensory thresholds and consequent quicker reflex responses which would be brought about by a more or less continuous stimulation of the adrenal cortex.

When the figures are broken down there appears one sad feature, smallpox, the disease which we have known how to prevent for a hundred and forty years, was unusually prevalent in the country at large. If compulsory vaccination against smallpox cannot be contrived one must wonder how effectively compulsory health insurance can be expected to assert itself under the Stars and Stripes, preventive medicine and human nature being what they are. Even these discrepancies however may serve a useful purpose by still further stimulating our natural supplies of adrenaline, and may thus bring about an even happier chart for 1939!

In all seriousness, this phenomenon must not be misinterpreted. The knowledge we have can only partially explain what is taking place. These accumulating values provide a potential bandwagon. Already we have seen them pointed to with pride by various groups. They must not be lightly interpreted, either by ourselves or others.

## TULAREMIA

TULAREMIA is not a major health problem in the United States, but the subject is interesting inasmuch as the majority of cases can be prevented by reasonable precautions. According to Dr. A. M. Stimson, in a release from the United States Public Health Service dated December 23, 1938, totals of 8000 cases and 396 deaths had been reported up to 1938, furthermore, 613 cases had been recorded in 1938 up to November 1, not including the figures from Illinois, Ohio, Virginia and Kentucky where, for the past twelve years, high incidences have occurred.

New England has been singularly free from the disease. As pointed out elsewhere in this issue of the *Journal*, only 4 cases have been recorded,—

Heart Disease The treatment of heart attacks' or 'cardiovascular emergencies'	February 23
Operative Obstetrics	March 2
The Control and Treatment of Respiratory Infections (This is to include the serological treatment of pneumonia in infants and children.)	March 9
Gonorrhea Modern treatment of gonorrhea	March 16
Syphilis Latent syphilis—diagnosis and treatment	March 23
Bleeding in the Third Trimester of Pregnancy	March 30

Meetings to be held at the Morton Hospital, Thursdays, at 4 00 p m.

Walter H. Flanders, M.D., *Chairman*

universal practice to introduce a bag if labor did not follow rupture of the membranes within twenty-four hours. In this case it was not done. Today, when it is known that there is no pelvic disproportion, most men are indifferent to the early rupture of the membranes, because experience has taught that the great majority of such cases will start in satisfactory labor even if there is a delay of three to five days before the onset of labor. Occasionally such an occurrence does result in a prolonged, unsatisfactory labor, and any such patient may experience postpartum hemorrhage.

Version was done in this case because the head was not low, the cervix was not completely dilated, and satisfactory progress was not being made. The operation of version in primiparas must always be undertaken with an appreciation of its inherent dangers and should not be performed by one poorly trained in the art of obstetrics.

Apparently the placenta separated very soon after the birth of the baby and may have been partially separated before the baby was born. Evidence of this was the large clot and unusual amount of fresh bleeding which immediately followed the delivery of the placenta.

The periods of relaxation in this uterus were much longer than those of contraction, and there was apparently considerable bleeding during the former, which resulted in the loss of more blood than was normal. Transfusion not only replaced lost blood but, as so often happens, stimulated the uterus to contract. Neither the amount of bleeding nor the condition of the uterus made packing necessary. The excellent result following transfusion proved this to have been the correct procedure.

## LEGISLATIVE NOTES

The following bills before the Legislature are scheduled for a public hearing before the Committee on Public Health on February 9.

SENATE 258 Bill relative to the meaning of the terms 'rendering medical service,' 'practice of medicine,' et cetera

HOUSE 59 Same as S 258

HOUSE 60 Bill relative to the annual registration of physicians

HOUSE 985 Bill relative to doctors of medicine and doctors of osteopathy on the Board of Registration in Medicine.

HOUSE 986 Bill relative to a doctor of medicine and a doctor of osteopathy on the Approving Authority

## POSTGRADUATE EXTENSION COURSES

The programs of instruction to be given this spring by the Massachusetts Medical Society in cooperation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau are listed below. These courses are offered free to all legally registered physicians in Massachusetts.

### BARNSTABLE DISTRICT

#### Place HYANNIS

SUBJECT	DATE
Bleeding in the Third Trimester of Pregnancy	March 5
Heart Disease The treatment of heart attacks or "cardiovascular emergencies"	March 12
Syphilis Latent syphilis—diagnosis and treatment	March 19
Gonorrhea Modern treatment of gonorrhea	March 26
Cesarean Section, Analgesia	April 2
The Indications and Contraindications for Removal of Tonsils and Adenoids	April 9
Anemia Modern methods in diagnosis and treatment of blood dyscrasias	April 16
Bright's Disease and Hypertension Evaluation of new therapy, diagnosis	April 23

Meetings to be held at the Cape Cod Hospital, Sundays, at 4 00 p m

Donald E Higgins, M.D., *Chairman*

### BERKSHIRE DISTRICT

#### Place PITTSFIELD

SUBJECT	DATE

## FACULTY

*Anemia* Chairman Dr William P Murphy Instructors Drs Greene FitzHugh, Clark W Heath, Chester S Keefer, George R. Minot and Maurice B Strauss

*Bright's Disease and Hypertension* Chairman Dr James P O'Hare. Instructors Drs Laurence B Ellis, W Richard Ohler and Robert S Palmer

*Heart Disease* Chairman Dr Paul D White. Instructors Drs Edward F Bland, Francis L Chamberlain, Wilfrid J Comeau, Marshall N Fulton, R. Earle Glendy, Ashton Graybiel, Burton E Hamilton, T Duckett Jones, Samuel A Levine, Benedict F Massell, Sylvester McGinn, Joseph H. Pratt, William D Reid, Howard B Sprague and Oliver H. Stansfield.

*Gonorrhea* Chairman Dr E Granville Crabtree. Instructors Drs Weston T Buddington, Fletcher H Colby,

Oscar F Cox, Jr, Roger C Graves, Sylvester B Kelley, George C Prather and Samuel N Vose.

*Syphilis* Chairman Dr E. Granville Crabtree. Instructors Drs William P Boardman, Rudolph Jacoby, C. Guy Lane and Francis M Thurmon

*Obstetrics* Chairman Dr Robert L. DeNormandie. Instructors Drs De Los J Bristol, Jr, Christopher J Duncan, M Fletcher Eades, A. Gordon Gauld, Thomas R. Goethals, Roy J Heffernan, James C Janney, M. V Kappus, Foster S Kellogg, Joseph W O'Connor, John Rock, Judson A Smith and Raymond S Titus

*Pediatrics* Chairman Dr Warren R. Sisson. Instructors Drs James M Baty, Allan M. Butler, Stewart H. Clifford, John Davies, Louis K. Diamond, R. Cannon Eley, Carlyle G. Flake, Joseph Garland, Harold L. Higgins, Charles I. Johnson, Charles F. McKhann, Edwin H. Place, Clement A. Smith and Edwin T. Wyman

MEDICAL POSTGRADUATE  
EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning February 6

## BRISTOL NORTH

Thursday, February 9, at 4 00 p m., at the Morton Hospital, Taunton Subject—Anemia Modern methods in diagnosis and treatment of blood dyscrasias Instructor Maurice B Strauss Lester E. Butler, *Chairman*

## BRISTOL SOUTH (Fall River Section)

Tuesday, February 7, at 4 00 p m., at the Union Hospital, Fall River Subject—Gonorrhea Modern treatment of gonorrhea. Instructor Oscar F Cox, Jr Howard P Sawyer, *Chairman*

## MIDDLESEX EAST

Tuesday, February 7, at 4 00 p m., at the Melrose Hospital (Colby Hall), Melrose. Subject—Medical Complications in Pregnancy Instructor James C Janney Walter H Flanders, *Chairman*

## MIDDLESEX NORTH

Thursday, February 9, at 4 30 p m., at St. John's Hospital, Lowell Subject—The Indications and Contraindications for Removal of Tonsils and Adenoids Instructor Warren R. Sisson William S Lawler, *Chairman*

## DEATHS

CLARK—GEORGE S CLARK, M.D., of 12 German Street, Worcester, died January 27 He was in his eightieth year

Born in Hardwick, he graduated from Hitchcock Free High School and taught school for several years He received his degree from the Harvard Medical School in 1885 Dr Clark was a member of the American Medical Association and the Massachusetts Medical Society and had practiced medicine in Worcester for fifty seven years.

His widow, four daughters, a sister and two brothers survive him

**EMERY**—**WILLIAM H. EMERY, M.D.**, of 109 Warwick Street, Roxbury, died January 21. He was in his ninety-first year.

Dr Emery received his degree from the Harvard Medical School in 1870 and, in his younger days, was an associate of Dr Oliver W Holmes.

He was a member of the Massachusetts Medical Society and the American Medical Association.

**FERNALD**—**GUY G. FERNALD, M.D.**, of Elm Street, West Concord, died January 26. He was in his seventy-fifth year.

Born in Wilton, Maine, he attended Wilton Academy, State Normal School, St. Johnsbury Academy and Dartmouth College and, in 1899, received his degree from the Dartmouth Medical School. He served his internship at Mary Hitchcock Memorial Hospital, Hanover, New Hampshire, and then joined the staff of the McLean Hospital at Waverley. In 1908 he went to the Massachusetts Reformatory Hospital at West Concord where he remained for twenty-seven years. Dr Fernald served as principal in the boys division at the Perkins Institute for the Blind, disciplinarian at Friends School, Providence, and while at the reformatory organized the psychopathological laboratory.

He was a member of the Massachusetts Medical Society and the American Medical Association.

His widow, a son and two brothers survive him.

**SEGUR**—**WILLARD B. SEGUR, M.D.**, of Enfield, died January 27. He was in his seventy-fourth year.

Dr Segur graduated from Phillips Andover Academy and Princeton University, and received his degree from Dartmouth Medical School in 1892. For many years he practiced medicine in the Quabbin Valley area and had been medical examiner of the fourth Hampshire district for the past twenty years.

He was a fellow of the American Medical Association and of the Massachusetts Medical Society.

His widow and a son survive him.

**WOODWARD**—**LEROY A. WOODWARD, M.D.**, of 5 High Street, Worcester, died January 22. He was in his fifty-fifth year.

Dr Woodward attended the public schools in Pawtucket, Rhode Island, and later entered the Rhode Island College of Pharmacy, graduating in 1906. He graduated from Tufts College Medical School in 1914 and interned at the House of Mercy Hospital, Pittsfield, and the Worcester City Hospital. He was chief surgeon at the Harvard Private Hospital, Worcester.

He was a fellow of the Massachusetts Medical Society and the American Medical Association.

MISCELLANY

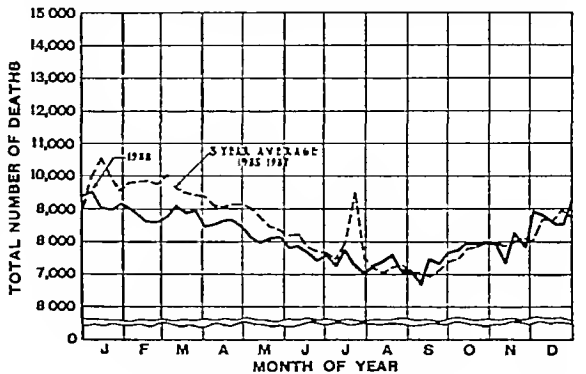

ANNUAL MORTALITY SUMMARY FOR 1938

Deaths in eighty-eight major cities during 1938 were 6 per cent under the 1937 figures, according to preliminary reports recently made public by Director William L. Austin, of the Bureau of the Census, Department of Commerce. The infant death rate in these cities was also slightly lower last year compared with 1937.

Deaths in the eighty-eight cities in 1938 totaled 424,189 compared with 449,555 reported for 1937, which is a decrease of 5.6 per cent. The provisional infant mortality rate for the eighty-eight cities is 43 per 1000 live births, compared with 47 in 1937.

The weekly death totals reported in 1938 were consistently lower than the average totals for the preceding three years from January to July, inclusive. During the rest of the year, however, the 1938 weekly totals were closely similar to the averages of the preceding three years.

The more favorable mortality record of 1938 as compared with the average of the preceding three years is due, probably, to the smaller number of deaths from in-

Total Deaths by Weeks in Eighty Eight Major Cities of the United States

fluenza and pneumonia during the winter and to the less extreme heat conditions during the summer.

The 27,147 infant deaths reported for 1938 represent a decrease of 1598, or 5.6 per cent, from the 28,745 reported for 1937. On the basis of estimated number of births, there were, in 1938, 43 infant deaths for each 1000 births. Although this figure is provisional, it indicates a real decrease in infant mortality when compared with the comparable provisional rate of 47 for 1937.

In the comparison of infant rates for different cities, certain considerations must not be overlooked. Primarily, the effect of differences in sex, age and racial composition of different cities must be evaluated before valid comparisons can be made.

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR NOVEMBER, 1938

DISEASES	NOV 1938	NOV 1937	FIVE YEAR AVERAGE*
Anterior poliomyelitis	0	6	16
Chickenpox	811	973	976
Diphtheria	21	8	43
Dog bite	666	598	540
Dysentery bacillary	9	37	68
German measles	30	39	61
Gonorrhea	421	589	544
Lobar pneumonia	233	269	300
Measles	597	282	482
Meningococcus meningitis	2	5	5
Mumps	257	266	347
Paratyphoid B fever	12	6	2
Scarlet fever	356	594	627
Syphilis	503	558	453
Tuberculosis, pulmonary	262	275	266
Tuberculosis other forms	30	24	28
Typhoid fever	6	15	8
Undulant fever	5	2	3
Whooping cough	558	471	758

Based on figures for preceding five years.

RARE DISEASES

*Anthrax* was reported from Somerville, 1, total, 1.

*Diphtheria* was reported from Boston, 1, Burlington, 1, Cambridge, 1, Gloucester, 1, Groveland, 1, Fall River, 3, Lawrence, 10, Medford, 1, Methuen, 1, North Andover, 1, total, 21.

*Dysentery bacillary* was reported from Amherst, 1,

Beverly, 1, Boston, 2, Danvers, 1, Lowell, 1, New Bedford, 1, Norwood, 1, West Springfield, 1, total 9

*Infectious encephalitis* was reported from Chelmsford, 1, Chelsea, 1, Foxboro, 1, Middleboro, 1, total, 4

*Meningococcus meningitis* was reported from Marblehead, 1, West Townsend, 1, total, 2

*Paratyphoid B fever* was reported from Lynn, 4, Medford, 1, Springfield, 2, Wellesley, 1, West Bridgewater, 3, Williamsburg, 1, total, 12

*Pellagra* was reported from Revere, 1, total, 1

*Septic sore throat* was reported from Boston, 5, Lawrence, 3, Marblehead, 1, Woburn, 1, total, 10

*Trachoma* was reported from Boston, 1, Fitchburg, 1, Worcester, 1, total, 3

*Trichinosis* was reported from Boston, 1, Fall River, 1, total, 2

*Typhoid fever* was reported from Boston, 1, Chelsea, 1, Holyoke, 1, Ludlow, 3, total, 6

*Undulant fever* was reported from Boston, 1, Brockton, 1, Dalton, 1, Fitchburg, 1, Millbury, 1, total, 5

Anterior poliomyelitis showed record low incidence. Measles and tuberculosis (other forms) were reported above the five year average.

Lobar pneumonia, pulmonary tuberculosis, mumps and diphtheria were reported below the five-year average. *Meningococcus meningitis* showed record low figures except for the years 1925 and 1934 which were equalled. Chickenpox, German measles and scarlet fever were reported below the five year average. Undulant fever showed record high figures except for the year 1936 which was equalled. Paratyphoid B fever was reported at a record high figure.

Animal rabies continued to show low incidence. New foci were noted in Newbury and Haverhill

### "YOUR HEALTH" BROADCASTS

The next series of "Your Health" broadcasts, sponsored by the American Medical Association and the National Broadcasting Company and heard over the Blue Network each Wednesday at 2 00 p m, is entitled "Health for Tomorrow". It consists of four broadcasts as follows:

February 8 Avoiding Arthritis

Known factors in the causation of arthritis, its care.

February 15 Healthy Hearts

Known ways of protecting the heart against infection and hygienic abuse, how to live with heart disease.

February 22 Cancer Can Be Cured.

Known factors in the cause, prevention and treatment of cancer

March 1 Diabetes

Individual efforts plus medical aid win against diabetes

## CORRESPONDENCE

### AN ADVOCATE OF SOCIALIZED MEDICINE

To the Editor The medical profession faces a serious situation, a menace to the very existence of the doctor. The menace consists in the disorganized and disappearing practice of the doctors. This is partly caused, partly aggravated, by commercial competition of private clinics, hospitals, dispensaries, sanatoriums, medical centers, foundations, insurance and industrial medical departments, teaching clinics and hospitals, lodge and contract practice, fed-

eral, state and municipal public health departments, city hospitals, state favored private medical services and organizations, physicians holding more than one paying position, not to mention all the various cults, commercial quackery, counter-prescribing by druggists, self treatment and, last but not least, a poor and inadequate social service to investigate each case which applies for free treatment.

The doctor cannot solve his problem by evading the issue or romancing about it. He must face the realities of economic and medical life. The prevailing general economic conditions of depression have still more accentuated the sad state of the doctor. The doctor must organize properly to meet conditions as they now exist with his fellows and, if need be, apply liberal or even radical remedies, because the powers to be of the American Medical Association together with those physicians holding key positions, fear the loss of their prestige and therefore are not interested, or at least do not show it, taking in consideration what they say and even write with their pens, to help the physician and see to it that no physician is starving. I might say here that there are many physicians, yes thousands or more, who find it very difficult to pay rent, forgetting about meeting the ordinary everyday necessities of life, due to no fault of their own but for causes as stated before. The day of so-called "rugged individualism" is gone forever and has left "ragged individuals."

Thousands of persons, or to be exact, as our able and efficient Surgeon General of United States, Thomas Parran, said in his annual report, 40,000,000 people in the United States, the lower economic third of our population, are unable to provide themselves with medical care during serious illness, and the country is short 360,000 hospital beds. Many people are ashamed to ask for free medical care, others can only afford to pay a small fee, others cannot pay what they feel the physician should get, therefore they all lack medical care.

Private competitive practice is an anachronism and a failure, because the private physician cannot compete with the aforementioned causes and must gradually die by the wayside.

Unless and until the practice of medicine returns to where it rightfully belongs, namely to the private practicing physician, and before such is possible, all hospital plans over the country must be abolished, and all abuses in our hospitals, outpatient departments, and so forth, must meet the same ordeal together with what I have already set forth in my first paragraph, and by so doing the physician can again begin earning a living, then only would the medical economic upset subside. After carefully observing, for the past ten years, the gradual loss of more and more private medical practice, there is only one salvation, and that is the acceptance by the medical profession as a whole the help by the federal government under specific rules and regulations and pay each and every physician who is willing, and God only knows more than a majority of the physicians are willing, to be paid a stipulated reasonable salary and the physicians in turn will treat the needy individuals.

The federal government has already undertaken to spend \$850,000,000 and that sum will be increased depending on conditions. To give you one specific instance, \$3,000,000 was appropriated for venereal control, and now Dr. Parran is requesting the sum be increased gradually to \$25,000,000 a year.

If the medical profession will not give immediate consideration to what the federal government has already pledged itself to do, namely a square and fair deal to the

backbone of the medical profession (general practitioners), and not play with time, by waiting to see what may or will result in the pending government's case for alleged violation of antitrust laws against the American Medical Association and against others, organized medicine will treat its colleagues to a total economic disaster. The doctors should and must have a clear and true understanding of the real situation that is facing them, a realization of the actual causes and the logical cure of this present serious condition. Do not stand on the side lines and be unconcerned because you are earning a living. Unite, give a helping hand to all members of the medical profession, because many of them are worse off than those who apply for medical aid!

Practically all articles printed in our medical journals have never to date stated the actual true facts, but they have always clouded the real issues. The medical profession must awake from its lethargy, or accept defeat.

BERNARD ZUCKERMAN, M.D.

978 Blue Hill Avenue,  
Dorchester, Mass.

#### APPOINTMENT TO BOARD OF REGISTRATION IN MEDICINE

*To the Editor* This is to inform you that Dr. Dominzio A. Costa, 261 Hanover Street, Boston, having been appointed by former Governor Hurley as a member of the Board of Registration in Medicine, qualified on December 16, 1938

STEPHEN RUSHMORE, M.D., *Secretary*

Board of Registration in Medicine,  
State House, Boston.

According to statutory requirements, it was necessary for Dr. Costa to resign from the Massachusetts Medical Society to become eligible for appointment to the Board. Ed

#### REPORTS OF MEETINGS

##### MEETING IN HONOR OF PRESIDENT CARMICHAEL

A Tufts College Medical School faculty meeting in honor of President Leonard Carmichael, of Tufts College, was held Wednesday, February 1, at 6:30 p. m., at the Algonquin Club in Boston.

A pageant, depicting medical affairs at the time of the founding of the School in 1893, and during its first few years, was one of the features of the evening.

A. Warren Stearns, M.D., dean of the medical school, was chairman of the dinner arrangements and was assisted by Louis E. Phaneuf, M.D., professor of gynecology. Benjamin Spector, M.D., professor of anatomy, directed the pageant.

##### EASTERN HAMPDEN MEDICAL ASSOCIATION

The stated monthly meeting of the Eastern Hampden Medical Association was held on January 12 at the Oaks Hotel in Springfield.

The paper of the evening, entitled "Some Common Mistakes," was presented by Dr. Erdix T. Smith, of Springfield. He pointed out some commonly made errors in diagnosis and treatment and especially decried the handling of fracture cases by some of the younger men with inadequate training along these lines. He suggested

that a competent consultant should be called in order to avoid protracted and permanent disability in these cases.

A general discussion of the paper followed, led by Dr. Richard E. Dickson, of Holyoke.

J. JOSEPH KLAR, M.D., *Secretary*

#### NOTICES

##### REMOVAL

W. FENN HOYT, M.D., announces the removal of his office to 11 High Street, Springfield.

##### ANNOUNCEMENT

WILLIAM K. NANCE, M.D., who for the past two years has been a member of the resident staff of the Ring Sanatorium and Hospital, has opened an office at 7 Park Circle, Arlington Heights. Associated with him is Doris Hoffman, M.D.

##### JOHN T. BOTTOMLEY SOCIETY

The next meeting of the John T. Bottomley Society will be held in the Out Patient Department of the Carney Hospital on Tuesday, February 7, at 11:30 a. m.

##### PROGRAM

Care of the Feet in Diabetes. Dr. George Cleary  
Advantages and Disadvantages of Protamine Insulin.  
Dr. Charles Finnerty

WILLIAM J. MACDONALD, M.D., *Secretary*

##### BOSTON CITY HOSPITAL

The monthly clinicopathological conference will be held at the Boston City Hospital on Wednesday, February 8, at 12 o'clock noon, in the Pathological Amphitheater.

JOSEPH E. HALLISEY, M.D., *Secretary*  
Medical Staff.

##### NEW ENGLAND DERMATOLOGICAL SOCIETY

The next meeting of the New England Dermatological Society will be held on Wednesday, February 8, at 2:00 p. m., in the Skin Out Patient Department of the Massachusetts General Hospital. Following the clinical meeting, dinner will be served at the Hotel Kenmore.

The guest speaker at the dinner will be Dr. E. William Abramowitz, associate professor of dermatology and syphilology at the New York Post-Graduate Medical School, Columbia University. The subject will be "Remarks on the Action of Certain Drugs in the Local and General Treatment of Various Dermatoses."

Reservations for the dinner should be made with the secretary.

BERNARD APPEL, M.D., *Secretary*

##### GREATER BOSTON MEDICAL SOCIETY

There will be a meeting of the Greater Boston Medical Society at the Beth Israel Hospital on Tuesday evening, February 7, at 8:15.

Dr. Soma Weiss will speak on "Etiological Factors and Therapeutic Measures in Circulatory Collapse and Shock." Discussion by Drs. Herrman L. Blumgart, Charles G. Mixer and Jacob Fine will follow.

LOUIS M. FREEDMAN, M.D. *President*  
DAVID B. STEARNS, M.D., *Secretary*

Beverly, 1, Boston, 2, Danvers, 1, Lowell, 1, New Bedford, 1, Norwood, 1, West Springfield, 1, total 9

*Infectious encephalitis* was reported from Chelmsford, 1, Chelsea, 1, Foxboro, 1, Middleboro, 1, total, 4

*Meningococcus meningitis* was reported from Marblehead, 1, West Townsend, 1, total, 2

*Paratyphoid B fever* was reported from Lynn, 4, Medford, 1, Springfield, 2, Wellesley, 1, West Bridgewater, 3, Williamsburg, 1, total, 12

*Pellagra* was reported from Revere, 1, total, 1

*Septic sore throat* was reported from Boston, 5, Lawrence, 3, Marblehead, 1, Woburn, 1, total, 10

*Trachoma* was reported from Boston, 1, Fitchburg, 1, Worcester, 1, total, 3

*Trichinosis* was reported from Boston, 1, Fall River, 1, total, 2

*Typhoid fever* was reported from Boston, 1, Chelsea, 1, Holyoke, 1, Ludlow, 3, total, 6

*Undulant fever* was reported from Boston, 1, Brockton, 1, Dalton, 1, Fitchburg, 1, Millbury, 1, total, 5

Anterior poliomyelitis showed record low incidence. Measles and tuberculosis (other forms) were reported above the five-year average.

Lobar pneumonia, pulmonary tuberculosis, mumps and diphtheria were reported below the five year average. *Meningococcus meningitis* showed record low figures except for the years 1925 and 1934 which were equaled. Chickenpox, German measles and scarlet fever were reported below the five-year average. Undulant fever showed record high figures except for the year 1936 which was equaled. Paratyphoid B fever was reported at a record high figure.

Animal rabies continued to show low incidence. New foci were noted in Newbury and Haverhill

### "YOUR HEALTH" BROADCASTS

The next series of 'Your Health' broadcasts, sponsored by the American Medical Association and the National Broadcasting Company and heard over the Blue Network each Wednesday at 2 00 p m., is entitled *Health for Tomorrow*. It consists of four broadcasts as follows

February 8 Avoiding Arthritis

Known factors in the causation of arthritis, its care.

February 15 Healthy Hearts.

Known ways of protecting the heart against infection and hygienic abuse, how to live with heart disease.

February 22 Cancer Can Be Cured

Known factors in the cause, prevention and treatment of cancer

March 1 Diabetes

Individual efforts plus medical aid win against diabetes

## CORRESPONDENCE

### AN ADVOCATE OF SOCIALIZED MEDICINE

To the Editor The medical profession faces a serious situation, a menace to the very existence of the doctor. The menace consists in the disorganized and disappearing practice of the doctors. This is partly caused, partly aggravated, by commercial competition of private clinics, hospitals, dispensaries, sanatoriums, medical centers, foundations, insurance and industrial medical departments, teaching clinics and hospitals, lodge and contract practice, fed-

eral, state and municipal public health departments, city hospitals, state favored private medical services and organizations, physicians holding more than one paying position, not to mention all the various cults, commercial quackery, counter prescribing by druggists, self treatment and, last but not least, a poor and inadequate social service to investigate each case which applies for free treatment.

The doctor cannot solve his problem by evading the issue or romancing about it. He must face the realities of economic and medical life. The prevailing general economic conditions of depression have still more accentuated the sad state of the doctor. The doctor must organize properly to meet conditions as they now exist with his fellows and, if need be, apply liberal or even radical remedies, because the powers to be of the American Medical Association together with those physicians holding key positions, fear the loss of their prestige and therefore are not interested, or at least do not show it, taking in consideration what they say and even write with their pens, to help the physician and see to it that no physician is starving. I might say here that there are many physicians, yes thousands or more, who find it very difficult to pay rent, forgetting about meeting the ordinary everyday necessities of life, due to no fault of their own but for causes as stated before. The day of so-called 'rugged individualism' is gone forever and has left 'ragged individuals'.

Thousands of persons, or to be exact, as our able and efficient Surgeon General of United States, Thomas Parran, said in his annual report, 40,000,000 people in the United States, the lower economic third of our population, are unable to provide themselves with medical care during serious illness, and the country is short 360,000 hospital beds. Many people are ashamed to ask for free medical care, others can only afford to pay a small fee, others cannot pay what they feel the physician should get, therefore they all lack medical care.

Private competitive practice is an anachronism and a failure, because the private physician cannot compete with the aforementioned causes and must gradually die by the wayside.

Unless and until the practice of medicine returns to where it rightfully belongs, namely to the private practicing physician, and before such is possible, all hospital plans over the country must be abolished, and all abuses in our hospitals, outpatient departments, and so forth, must meet the same ordeal together with what I have already set forth in my first paragraph, and by so doing the physician can again begin earning a living, then only would the medical economic upset subside. After carefully observing, for the past ten years, the gradual loss of more and more private medical practice, there is only one salvation, and that is the acceptance by the medical profession as a whole the help by the federal government under specific rules and regulations and pay each and every physician who is willing, and God only knows more than a majority of the physicians are willing, to be paid a stipulated reasonable salary and the physicians in turn will treat the needy individuals.

The federal government has already undertaken to spend \$850,000,000 and that sum will be increased depending on conditions. To give you one specific instance, \$3,000,000 was appropriated for venereal control, and now Dr. Parran is requesting the sum be increased gradually to \$25,000,000 a year.

If the medical profession will not give immediate consideration to what the federal government has already pledged itself to do, namely a square and fair deal to the

backbone of the medical profession ('general practitioners'), and not play with time, by waiting to see what may or will result in the pending government's case for alleged violation of antitrust laws against the American Medical Association and against others, organized medicine will treat its colleagues to a total economic disaster. The doctors should and must have a clear and true understanding of the real situation that is facing them, a realization of the actual causes and the logical cure of this present serious condition. Do not stand on the sidelines and be unconcerned because you are earning a living. Unite, give a helping hand to all members of the medical profession, because many of them are worse off than those who apply for medical aid!

Practically all articles printed in our medical journals have never to date stated the actual true facts, but they have always clouded the real issues. The medical profession must awake from its lethargy, or accept defeat.

BERNARD ZUCKERMAN, M.D.

978 Blue Hill Avenue,  
Dorchester, Mass

#### APPOINTMENT TO BOARD OF REGISTRATION IN MEDICINE

*To the Editor* This is to inform you that Dr Dominzio A. Costa, 261 Hanover Street, Boston, having been appointed by former Governor Hurley as a member of the Board of Registration in Medicine, qualified on December 16, 1938

STEPHEN RUSHMORE, M.D., *Secretary*

Board of Registration in Medicine,  
State House, Boston.

According to statutory requirements, it was necessary for Dr Costa to resign from the Massachusetts Medical Society to become eligible for appointment to the Board. Ed

## UROLOGICAL CONFERENCE

A urological conference will be held at 12 o'clock noon on the first and third Fridays of February, March, April and May in the Lower Out Patient Amphitheater of the Massachusetts General Hospital.

AMERICAN BOARD OF OBSTETRICS  
AND GYNECOLOGY, INCORPORATED

The general oral, clinical and pathological examinations for all candidates, Part 2 examinations (Groups A and B), will be conducted by the entire board, meeting in St. Louis, Missouri, on May 15 and 16, immediately prior to the annual meeting of the American Medical Association. Notice of time and place of these examinations will be forwarded to all candidates well in advance of the examination dates.

Candidates for re-examination in Part 2 (Groups A and B) must request such re-examination by writing the secretary's office before April 1. Candidates who are required to take re-examinations must do so before the expiration of three years from the date of their first examination.

The annual dinner meeting of the board, to which all diplomates and candidates are invited, as well as their wives and others interested in the work of the board, will be held at the Congress Hotel, St. Louis, on Wednesday evening, May 17, following the close of the examinations.

Application for admission to the Group A examinations must be on file in the secretary's office not later than March 15. Application blanks and booklets of information may be obtained from Dr Paul Titus, secretary, 1015 Highland Building, Pittsburgh (6), Pennsylvania.

## TUMOR CLINIC, BOSTON DISPENSARY

Each Tuesday and Friday morning, 10 00 to 12 30, there is a meeting of the Tumor Clinic of the Boston Dispensary, a unit of the New England Medical Center. Neoplasms of various sorts are seen and discussed, and when there is an indication, are treated with radium of high-voltage x-ray. Physicians are invited to visit this clinic. They may bring patients for aid in diagnosis or may refer patients to the clinic following which a report will be returned to the referring physician. A limited number of beds are available for diagnostic study and for treatment.

MEDICAL CLINIC AT THE PETER BENT  
BRIGHAM HOSPITAL

At 3 30 p m on Thursday, February 9, in the amphitheater of the Peter Bent Brigham Hospital, Dr C Sidney Burwell, research professor of clinical medicine and dean, Harvard Medical School and physician, Peter Bent Brigham Hospital, will give a medical clinic. Practitioners and medical students are cordially invited to attend.

## TEMPERATURE SYMPOSIUM

A symposium on "Temperature and Its Measurement in Science and Industry" will be held under the auspices of the American Institute of Physics, probably next fall, the dates to be announced later. Consistent with the title, the symposium will broadly cover many fields, its primary purposes according to present plans being to (1) co-ordinate the treatment of the subject in the sciences and branches of engineering, (2) review principles and bring up to date the record of recent work, (3) accumulate contributions for a comprehensive text, to be published as soon as possible after the symposium is held, (4) reveal the subject as an important branch of physics and (5) supply schools with the information required for the improvement of curricula. The Institute confidently expects that a stimulating, valuable and unified program will be arranged, an aim which will require the help of many contributors.

A representative steering committee has been formed consisting of the chairman, C O Fairchild, director of research, C J Tagliabue Manufacturing Co, Dr E F DuBois, medical director, Russell Sage Institute of Pathology and professor of medicine, Cornell University Medical College, Dr Gustav Egloff, director of research, Universal Oil Products Co, Dr John Johnston, director of research, United States Steel Corporation, Dr W G Whitman, head, Department of Chemical Engineering, Massachusetts Institute of Technology, and Dr H A Barton, director, American Institute of Physics.

Those who are interested in taking part in this symposium should communicate with the Institute at an early date, giving information regarding their field of work and the subject of the contribution they wish to make. Such contributions will be co-ordinated with the subjects of a group of invited papers, and assignments and divisions made. Further information for contributors will be available shortly. Address all communications to American Institute of Physics, 175 Fifth Avenue, New York City.

## HARVARD MEDICAL SCHOOL LECTURES

The following lectures will be given in Amphitheater C of the Harvard Medical School at 5 p m

February 9—Lecture on the Care of the Patient. Dr Donald Guthrie of Sayre, Pennsylvania  
February 16—George W Gay Lecture on Medical Ethics. Dr Robert L. DeNormandie.

## SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING  
MONDAY, FEBRUARY 6

## MONDAY FEBRUARY 6

4 p m Physicians and medical students are cordially invited to attend a clinic presented by the medical surgical and orthopedic services of the Infants and Children's hospitals in the amphitheater of the Children's Hospital.

## TUESDAY FEBRUARY 7

\*9 10 a m Joseph H Pratt Diagnostic Hospital. Diagnosis of Certain Shoulder Conditions. Dr J D Adams.

10 a m 12 30 p m Tumor clinic. Boston Dispensary.

11 30 a m John T Bottomley Society. Carney Hospital.

8 p m Robert B Brigham Hospital.

8 15 p m Greater Boston Medical Society. Beth Israel Hospital.

## WEDNESDAY FEBRUARY 8

\*9 10 a m Joseph H Pratt Diagnostic Hospital. Hospital case presentation. Dr S J Thannhauser.

12 m Clinicopathological conference. Children's Hospital Amphitheater.

12 m Boston City Hospital. Clinicopathological conference. Pathological Amphitheater.

2 p m New England Dermatological Society. Massachusetts General Hospital.

## THURSDAY FEBRUARY 9

- 8:30-9:30 a m Exchange visit Surgical and Orthopedic Staffs of the Peter Bent Brigham and Children's hospitals held this week at the Children's Hospital Surgical
- \*9:10 a m Joseph H Pratt Diagnostic Hospital The Present Status of Vitamin B Dr L. R. Weiss
- 3:30 p m Medical clinic at the Peter Bent Brigham Hospital
- 5 p m Lecture on the Care of the Patient Harvard Medical School Amphitheater C

## BOOK REVIEWS

*Cranio-Cerebral Injuries Their diagnosis and treatment*  
Donald Munro 412 pp London, New York and Toronto Oxford University Press, 1938 \$4.00

Dr Donald Munro, surgeon-in-chief for neurological surgery at the Boston City Hospital, has long been interested in injuries to the central nervous system. His large clinic, from which he reports over 1000 cases, has been a source of intensive study on the results of cerebral trauma. In addition, in associated departments of the hospital, experimental work has been carried forward which has added to our knowledge of intracranial pathology. The book, in review, is a personal report of the patients observed by him and the deductions drawn therefrom. The literature surveyed, in addition to his own publications, is largely, although not entirely, that emanating from the Boston City Hospital. This, however, should not detract from the value of the publication for it is Dr Munro's experiences and the conclusions which he has drawn from them that are of value.

The subject is extensively covered. Beginning with the fundamentals of cerebral physiopathology, the author considers the important questions of history and examination of patients, roentgenology, general principles of treatment, operative and non-operative treatment, complications of craniocerebral injuries, the complications due to necessary treatment, first aid, convalescent care and a general survey of his mortality and morbidity statistics. In addition, there is a chapter on craniocerebral injuries in the newborn.

In the opinion of the reviewer, no book covers the subject as well as this one. It is a practical, straightforward account of what has often been considered a field of great uncertainty. With the increasing number of automobile accidents, surgeons are forced, more and more, to handle patients with injuries of this type. Should they follow the outline set down by Dr Munro, their results, provided they have equal technical skill in operation, should be greatly improved over the results of a decade ago. There are, moreover, many practical hints for the general practitioner, who is the one that usually sees patients of this type first. The author stresses the importance of getting the patient to a hospital as soon as possible and of combating surgical shock before particular attention is given to the intracranial injury. As he states, if a patient cannot be moved or surgical shock is such that it becomes a serious factor, the patient is unlikely to survive even if operated on later. The value of absolute rest, the avoidance of early roentgenological examination, lumbar puncture, intravenous medication and intracranial operation are all considered in turn. One of the most

important parts of the book is the chapter on subdural hematomas, a traumatic condition which is often overlooked by general practitioners

Although there are hints about convalescent care, one wishes the author had said more about the prevention of one of the most serious complications of intracranial injury, namely traumatic neurosis. Can traumatic neurosis be differentiated from a postconcussional syndrome? As many patients, moreover, have difficulties with accident and other forms of insurance, one would wish the author had said even more about this aspect of the subject. Although, perhaps, the aim of the book is to instruct surgeons, the general title *Cranio-Cerebral Injuries Their diagnosis and treatment* would indicate that a wider expansion of the subject by the author was to be expected. It should be pointed out, moreover, that the surgeon is the one who is called on to give the reports to the insurance company and often to testify in court action.

It is hoped that in a second edition of this book, which is sure to be called for, an additional chapter summarizing the whole situation will be given. Without increasing the size of the book, it would seem to the reviewer that the last chapter containing so many case reports might either be shortened or these case reports put in smaller type, thus leaving room for a final summary.

*Doctor Bradley Remembers* Francis B. Young. 522 pp. New York: Reynal & Hitchcock, 1938. \$2.75.

This is a full length novel by a well known British author, who formerly practiced medicine. He is therefore fully familiar with the field of medical practice. The story briefly consists of the reminiscences of an old doctor just retiring from the practice of medicine. It depicts the education of a country doctor and his practice in a small English mining town. The character of Dr. Bradley is well drawn as is that of his family and the young physician who comes to him as an apprentice. Any physician will read this novel with pleasure. It should be pointed out, however, that so far as the public is concerned, erroneous impressions of medicine might be drawn by books of this type. This is also true of another novel, recently widely read, by Dr. Cronin. Although all that is put into these books is probably true, too much emphasis is put on the unfavorable side of medical practice. Dr. Young's book, however, is not so much to be criticized along these lines as other recent publications.

*Synopsis of Clinical Laboratory Methods* W. E. Bray. Second edition. 408 pp. St. Louis: C. V. Mosby Co., 1938. \$4.50.

Today there are a great many so-called laboratory handbooks. Most everyone working in the laboratory makes certain modifications of existing methods. Often these are incorporated as a laboratory manual and eventually present themselves as a handbook. This particular text is weak in respect to the present-day methods of blood chemistry, and the section on hematology is too detailed. The book is set up in type that is unusually difficult to read, and there are a good many typographical errors.

*Insulin: Its chemistry and physiology* Hans F. Jensen. 252 pp. New York: The Commonwealth Fund, 1938. \$2.00.

Dr. Jensen has written a very comprehensive monograph, not only with adequate references to the literature, but with a critical survey that is extremely valuable, coming as it does from one of the important workers in this field. He treats of the chemistry, biochemistry and

physiology of insulin in such a readable way that a reader is given an excellent general survey, even though the latter's training may not fit him to understand all the details.

For men who expect to use insulin intelligently and keep abreast of the literature, the book is extremely timely and indeed, an almost indispensable background, unless one has followed the literature in detail from the beginning.

*Urology* Daniel N. Eisendrath and Harry C. Rohndorf. Fourth edition, entirely revised and reset. 1061 pp. Philadelphia, Montreal and London: J. B. Lippincott Co., 1938. \$10.00.

The fact that this is the fourth edition of this book is evidence of its popularity in the past. The present edition has been brought up to date by the inclusion of added material such as the antiseptic action of sulfanilamide and mandelic acid, cystometry and excretion pyelography.

A new chapter on the medical aspects of nephritis is unfortunate because it has been impossible to do the subject justice in the allotted space. On the other hand the inclusion of a few pages on ailments of the urethra and bladder of women is to be commended.

The work as a whole forms a compendium of present urologic knowledge gleaned from a wide survey of the literature. It lacks, in too large measure, critical discussion based on the personal experience of the writers.

*A Textbook of Biochemistry For students of medicine and science* A. T. Cameron. Fifth edition. 414 pp. New York: The Macmillan Co., 1938. \$4.00.

The fifth edition of this text has been completely revised. Rewritten to include the rapid progress in biochemistry in the past few years, it deals with biochemical problems in a most lucid and clear manner. Dr. Cameron has the happy faculty of being able to explain without too much effort the underlying principles of most of the biochemical phenomena—a welcome text, indeed, in a field where the problems appear most intricate and confusing.

*The Seasonal Periodicity of Malaria and the Mechanism of the Epidemic Wave* Clifford A. Gill. 136 pp. London: J. & A. Churchill Ltd., 1938. 10s. 6d.

This modest little book on the epidemiology of malaria is unusually significant and, therefore, important.

In Part I, the author divides the world roughly into climatic zones of malaria. Each of these zones is characterized by stated features of temperature and of humidity which are significant with reference to the transmission of malaria. The epidemiological types of malaria in each of the four zones are discussed in Part II. The waves of malaria which occur in the spring and in the autumn or in both seasons are described. Part III, entitled "The General Properties of the Seasonal Wave," deals with its composition, periodicity, form, significance and mechanism. The last two chapters summarize some very important inferences which are well supported by the facts presented in the book.

The author points out that the anopheline factor and the meteorological factor, by reason of their influence on frequency of transmission, play important parts in the mechanism of the seasonal wave, but he believes that seasonal relapse is still more significant in the production of the seasonal wave. The cause of this pronounced tendency to seasonal relapse is still quite unknown.

## AN EPISODE IN MASSACHUSETTS IN 1818 RELATED TO THE TEACHING OF ANATOMY

FREDERICK C. WAITE, PH.D.\*

CLEVELAND, OHIO

THE recorded history of the study and teaching of anatomy in the United States began at Ipswich, Massachusetts, where, before 1647, was "made an anatomy for we never had but one Anatomy in the Countrey which Mr Giles Firmin did make and read upon very well"<sup>1</sup> In the seventeenth century "to make an anatomy" meant to complete a human dissection, and "to read upon" meant to lecture. Dr. Giles Firmin (circa 1614-1697), educated at Cambridge (England) University, came to the colony in 1632. He began medical practice in Ipswich in 1638, but after a few years returned to England, where he became a prominent clergyman.<sup>2</sup>

About a hundred and seventy-five years after Dr. Firmin "made his anatomy" at Ipswich there occurred in that part of the town known as Chebacco, which was set off in 1819 as the town of Essex, events that had some unusual features and which led indirectly to important promotions of medical education.

There was little teaching of practical anatomy in the colonial period, and that little was unknown outside the medical profession. Occasionally a preceptor with his pupils or a small group of physicians would dissect a body, but practical anatomy was unknown to the general public. In 1750 in New York City, Dr. John Bard and Dr. Peter Middleton dissected the body of an executed murderer.<sup>3</sup> They lectured over this dissection and there was some public disapproval. In 1754 William Hunter lectured on anatomy at Newport, Rhode Island, but it is not recorded that he exhibited dissections. There was no institutional teaching of anatomy until 1765. Therefore the question of dissection was not at all in the public mind, and there were no laws that provided material for the practical study of anatomy.<sup>11</sup> In colonial New England there were also no specific laws against the disturbance of graves.<sup>4</sup>

The founding of two colonial medical schools, in Philadelphia and in New York, and of the first medical school of the national period in Cambridge were in each case immediately preceded by courses in anatomy. Since institutional medical instruction was inaugurated by instruction in anatomy, that subject became in the public mind a salient feature of a medical school. Anatomy implied dissection, and since there were no legal provisions for securing bodies to dissect, a suspicion arose that establishment of a medical school would necessarily be accompanied by the disturbance of graves. The establishment of medical schools therefore brought the subject of grave-robbing into the public mind in the early national period. The practice was in such disrepute that at times mob action resulted, and two series of laws were passed. One series incidentally provided an extremely meager supply of material for dissection. In the other series appeared a vigorous legislative program to prohibit the disturbance of graves. The citations below of examples of these legislative actions are restricted to New England, but similar action was taken in other states where medical schools were established.

In 1784, there was passed in Massachusetts an "Act against Duelling." It provided that the body of one killed in a duel should be turned over to any surgeon who might apply for it to be dissected. In the absence of such request the body was to be buried in the most public highway near the scene of the duel, without a coffin and with a stake driven through the body.<sup>5, 6</sup> Thus dissection was made equivalent to the most disreputable burial that could be devised. Incidental to this attempt to stop dueling the law provided the first legal dissecting material in New England. The first lectures in Harvard Medical School were in the autumn of 1783, so that in its second year this school, theoretically, could provide legal instruction in practical anatomy, provided someone engaged in a duel

\*Professor of histology and embryology, School of Medicine, Western Reserve University, Cleveland, Ohio.

important parts of the book is the chapter on subdural hematomas, a traumatic condition which is often overlooked by general practitioners.

Although there are hints about convalescent care, one wishes the author had said more about the prevention of one of the most serious complications of intracranial injury, namely traumatic neurosis. Can traumatic neurosis be differentiated from a postconcussional syndrome? As many patients, moreover, have difficulties with accident and other forms of insurance, one would wish the author had said even more about this aspect of the subject. Although, perhaps, the aim of the book is to instruct surgeons, the general title *Cranio-Cerebral Injuries Their diagnosis and treatment* would indicate that a wider expansion of the subject by the author was to be expected. It should be pointed out, moreover, that the surgeon is the one who is called on to give the reports to the insurance company and often to testify in court action.

It is hoped that in a second edition of this book, which is sure to be called for, an additional chapter summarizing the whole situation will be given. Without increasing the size of the book, it would seem to the reviewer that the last chapter containing so many case reports might either be shortened or these case reports put in smaller type, thus leaving room for a final summary.

*Doctor Bradley Remembers* Francis B Young 522 pp  
New York Reynal & Hitchcock, 1938 \$2.75

This is a full length novel by a well known British author, who formerly practiced medicine. He is therefore fully familiar with the field of medical practice. The story briefly consists of the reminiscences of an old doctor just retiring from the practice of medicine. It depicts the education of a country doctor and his practice in a small English mining town. The character of Dr Bradley is well drawn as is that of his family and the young physician who comes to him as an apprentice. Any physician will read this novel with pleasure. It should be pointed out, however, that so far as the public is concerned, erroneous impressions of medicine might be drawn by books of this type. This is also true of another novel, recently widely read, by Dr Cronin. Although all that is put into these books is probably true, too much emphasis is put on the unfavorable side of medical practice. Dr Young's book, however, is not so much to be criticized along these lines as other recent publications.

*Synopsis of Clinical Laboratory Methods* W E Bray  
Second edition. 408 pp St. Louis C V Mosby Co,  
1938 \$4.50

Today there are a great many so-called laboratory handbooks. Most everyone working in the laboratory makes certain modifications of existing methods. Often these are incorporated as a laboratory manual and eventually present themselves as a handbook. This particular text is weak in respect to the present-day methods of blood chemistry, and the section on hematology is too detailed. The book is set up in type that is unusually difficult to read, and there are a good many typographical errors.

*Insulin Its chemistry and physiology* Hans F Jensen.  
252 pp New York The Commonwealth Fund,  
1938 \$2.00

Dr Jensen has written a very comprehensive monograph, not only with adequate references to the literature, but with a critical survey that is extremely valuable, coming as it does from one of the important workers in this field. He treats of the chemistry, biochemistry and

physiology of insulin in such a readable way that the reader is given an excellent general survey, even though the latter's training may not fit him to understand all the details.

For men who expect to use insulin intelligently and keep abreast of the literature, the book is extremely timely and, indeed, an almost indispensable background, unless one has followed the literature in detail from the beginning.

*Urology* Daniel N Eisendrath and Harry C. Rolnick  
Fourth edition, entirely revised and reset. 1061 pp.  
Philadelphia, Montreal and London J B Lippincott  
Co, 1938 \$10.00

The fact that this is the fourth edition of this book is evidence of its popularity in the past. The present edition has been brought up to date by the inclusion of added material such as the antiseptic action of sulfanilamide and mandelic acid, cystometry and excretion pyelography.

A new chapter on the medical aspects of nephritis is unfortunate because it has been impossible to do the subject justice in the allotted space. On the other hand the inclusion of a few pages on ailments of the urethra and bladder of women is to be commended.

The work as a whole forms a compendium of present urologic knowledge gleaned from a wide survey of the literature. It lacks, in too large measure, critical discussion based on the personal experience of the writers.

*A Textbook of Biochemistry For students of medicine and science* A. T. Cameron Fifth edition. 414 pp  
New York The Macmillan Co., 1938 \$4.00

The fifth edition of this text has been completely revised. Rewritten to include the rapid progress in biochemistry in the past few years, it deals with biochemical problems in a most lucid and clear manner. Dr Cameron has the happy faculty of being able to explain without too much effort the underlying principles of most of the biochemical phenomena. A welcome text, indeed, in a field where the problems appear most intricate and confusing.

*The Seasonal Periodicity of Malaria and the Mechanism of the Epidemic Wave* Clifford A. Gill. 136 pp  
London J & A. Churchill Ltd., 1938 10s 6d

This modest little book on the epidemiology of malaria is unusually significant and, therefore, important.

In Part I, the author divides the world roughly into climatic zones of malaria. Each of these zones is characterized by stated features of temperature and of humidity which are significant with reference to the transmission of malaria. The epidemiological types of malaria in each of the four zones are discussed in Part II. The waves of malaria which occur in the spring and in the autumn or in both seasons are described. Part III, entitled *The General Properties of the Seasonal Wave*, deals with its composition, periodicity, form, significance and mechanism. The last two chapters summarize some very important inferences which are well supported by the facts presented in the book.

The author points out that the anopheline factor and the meteorological factor, by reason of their influence on frequency of transmission, play important parts in the mechanism of the seasonal wave, but he believes that seasonal relapse is still more significant in the production of the seasonal wave. The cause of this pronounced tendency to seasonal relapse is still quite unknown.

catalogues stressed the use of charts and models in teaching anatomy, and in some cases dissection was not mentioned. When mentioned it was only to say that there was opportunity for such as desired to dissect. Many medical students depended upon their preceptors, rather than upon the medical school, to teach practical anatomy, and by the preceptors it was usually poorly taught.

The matter of dissecting material affected medical education and medical students in many ways. In several cases faculty dissension, which resulted in the founding of rival medical schools, first began over the question of defense or condemnation of students involved in a resurrection. By the laity every medical student was considered a potential, if not an actual, grave robber, and was considered of lower morality than students in other educational institutions. Medical students were inclined to try to live up to this reputation, and were given to drinking to excess, profanity and public boisterousness. They were less welcome in polite society than law students, theological students or students of colleges of arts. The current popular opinion of medical students is shown in a novel published in Boston in 1846 in which the chief characters are medical students and the concurrent themes are body snatching and prostitution.<sup>14</sup> The author was a student in Harvard Medical School when he wrote this, the third of a long list of works of fiction that bear his name.

When from 1826 to 1832 the Clinical School of Medicine at Woodstock, Vermont, was denied a charter by the legislature, one of the arguments used by local opponents of the granting of the charter was that a medical school in that vicinity was undesirable because it would lead to the violation of graves in the cemeteries of neighboring villages. The records of debates in the legislature show that several members of the Assembly said that if another medical school were to be established in the state they wanted it as far as possible from their home towns.<sup>15</sup>

Mob action in connection with dissection arose from time to time. The first recorded in the United States was in New York City in 1788. A large mob attacked and pillaged a dissecting room, and raised havoc for two days until dispersed by military force.<sup>3</sup>

In April, 1830, the grave of a young woman at Barnard, Vermont, was discovered to be empty. A large party of citizens assembled and marched to the Clinical School of Medicine, then in its first session at Woodstock, ten miles distant. They searched the medical building but did not find the body. Nevertheless four students were arrested on suspicion. Two of these were released

after preliminary examination and the other two were remanded for trial. At Woodstock in June, a jury brought in a verdict of not guilty.<sup>13</sup>

Before daylight on November 29, 1830, about three hundred men of Hubbardton, Vermont, and surrounding towns gathered in that village and, headed by the sheriff of the county, marched five miles to the town of Castleton. Here they searched the building of the Vermont Academy of Medicine, a medical school in that town, and found the body of a recently interred woman whose grave in Hubbardton had been found empty. In 1879 was celebrated at Castleton what was supposed to be the fiftieth anniversary of the 'Hubbardton Raid'. The error in date was discovered after the anniversary had been arranged. On this occasion the local physician immortalized the stirring events of 1830 in an epic poem of nearly five hundred lines written in the style of *Hiawatha*, a unique item in American medical literature.<sup>16</sup>

Mob action connected with unauthorized disinterment was not confined to New England. In the autumn of 1839 a crowd from a neighboring town attacked the medical school at Worthington, Ohio. They found two bodies. Thereupon the leaders of the mob directed the faculty to load all the movable possessions of the school into wagons, whereupon an armed group accompanied the wagons and the faculty to the county line and warned them never to return. They never did. Thus ended the medical school at Worthington.<sup>17 18</sup>

In February, 1852, in Cleveland, Ohio, a mob attacked the rooms on the upper floors of a business block occupied by the recently organized Western College of Homeopathic Medicine. No bodies were found, but the mob destroyed all the equipment of the school, damaged the building and attempted to burn it. The wreckage was so complete that the school never reoccupied the premises.<sup>19 20</sup> Meanwhile at the Medical Department of Western Reserve College, a half-mile distant, in anticipation of a similar attack, eighty muskets and ammunition were secured from a neighboring armory. The white-haired dean, musket in hand, stood on the front steps of the medical building, with his armed students behind him awaiting the mob, which did not come when its scouts advised it of the preparations for its reception. Instead it started for the residence of the dean of the Western College of Homeopathic Medicine, intent on destroying his private property, and was stopped only when met by a company of militia that had been hastily called out.

These half-dozen events in different parts of the country show the public resentment against what

in which one or both parties were killed, but the rarity of duels made this source of supply negligible. Twenty years later the available supply was extended to the bodies of executed murderers.

The Massachusetts law of 1805 provided that "justices in case of murder committed in a duel shall, and in other cases may, at their discretion, further sentence and order the body of such convict to be dissected and anatomized."<sup>7</sup> Here is specific evidence that dissection was considered an additional posthumous punishment for major crimes. There were more hangings than duels, but the fact that judges were not compelled to assign the bodies of criminals for dissection tended to make such material extremely scanty,—only one or two bodies a year,<sup>11</sup>—and a surgeon who had private pupils was just as likely to get the body as was the professor of anatomy of the medical school. In some years, the Harvard Medical School secured only one body. When, later, legal dissection was extended to the bodies of convicts dying in prison, this disposition was at the discretion of the prison commissioners, depending, among other things, on the nature of the crime which the convict had committed. The first law of this type in New England was passed in Connecticut in 1824. Here again dissection was an additional posthumous punishment.

The resultant popular conception of dissection as an additional penalty for major crimes made the subject of anatomy odious. The laity felt that dissection of the body of a friend stigmatized his memory and made him, by implication, a criminal. This sentiment inhibited the securing of laws to designate bodies buried at public expense for the use of students of anatomy, for people believed that this would stigmatize as a criminal one who was merely poor or unknown.

An example of the influence of the establishment of medical schools on the other phase of the legislative program, namely the prohibition of grave robbing, is that, coincident with the decision of Dartmouth College to inaugurate medical teaching, a law was passed in New Hampshire in 1796 which provided a penalty of \$1000, public flogging not to exceed thirty-nine stripes or imprisonment for one year for disturbing a grave.<sup>8</sup> A similar law was enacted in Vermont in 1804.<sup>9</sup>

Public flogging as a penalty ultimately disappeared from the laws, and fine and imprisonment varied in different states from \$100 to \$3000 for each offense, or imprisonment varying from one to ten years. In Massachusetts in 1818 the penalty was a fine of \$1000 or imprisonment for one year. The law imposed the same penalty for possession of a disinterred body as for the actual disinterment, and possession was defined as presence of the body under the control of an individual.<sup>10</sup>

The medical schools faced two alternatives either to abandon practical anatomy, since the sources of legally authorized material were insufficient to carry it on, or to conduct it with material secured by illegal methods. At the Harvard Medical School about 1810, "on account of the agitated state of the public mind concerning abuses in obtaining material for dissections . . . costly wax preparations were purchased to supersede the necessity of dissecting human subjects."<sup>11</sup> Officers of the medical schools tried in various ways to allay public agitation, which had brought prejudice against the medical school as an institution. One way was to attempt to persuade the local community, by proclamation, that the graves of families and friends were safe because material for dissection came from a distance. This argument was specious, certainly so before the era of railroads. Two examples of this method may be given.

At the Vermont Academy of Medicine at Castleton, 1824, the trustees passed the following resolutions:

Resolved by this corporation that no subject for use of this institution shall be taken from any graveyard or burying ground in the County, but such as may be necessary shall be procured from the great seaports of the neighboring States. Resolved that if any Student shall be guilty of violating the above Resolution, he shall be expelled from this Academy.<sup>12</sup>

This resolution was published in newspapers of the neighboring towns. In July, 1829, it was announced that the Clinical School of Medicine would open at Woodstock, Vermont, in the following March a published newspaper announcement, signed by the secretary of the faculty and school, contained the following:

We pledge ourselves to the community that we will not use or suffer to be used in any manner, so far as may come to our knowledge, any human body disinterred hereabouts — it may be invidious to set limits but we are willing to say the State of Vermont. We are well assured of obtaining a competency of the means from remote parts and in a manner that ever will be justified by the well informed and judicious part of the community.<sup>13</sup>

Because it was impossible to procure enough cadavers legally, the medical schools did not require dissection in the early nineteenth century, and in many schools not until late in that century. To do so implied a guarantee to furnish material which could be secured only by illegal methods. To make a requirement that implied law-breaking was likely to arouse public disapproval of medical schools, or even to endanger their charters. Therefore medical schools were careful as to what was said in print concerning dissection in connection with teaching, since medical school catalogues reached the laity as well as the profession. The

ber, 1819, a year and seven months after the discovery of the empty graves Daniel Davis, solicitor general of the Commonwealth, was attorney for the state and Daniel Webster for the defendant. The indictments charged that "Thomas Sewall did knowingly and wilfully receive, conceal, and dispose of the human body and remains thereof of one Sally Andrews" and "of one William Burnham." The charge was possession rather than disinterment. Dr Sewall was found guilty on both indictments, and was fined \$400 and costs in each case.<sup>27</sup>

Private resurrections are no longer practiced, since adequate anatomical laws have been enacted in all states, but this group of events, including the reburial of empty coffins and the proposed monument, constitute one of the most curious of the many public episodes connected with anatomical material. However, the interest in the events at Chebacco does not end with the trial of November, 1819, for there were two interesting sequels.

What of the man who was "largely fined"? Dr Thomas Sewall was born in Augusta, Maine, April 16, 1786, the son of a tanner. He studied medicine under a preceptor and began practice in Chebacco in 1808, succeeding his brother-in-law, Dr Reuben Dimond Mussey. For the session of 1810-11 Dr Sewall attended the Medical Department of the University of Pennsylvania, where Dr Mussey had recently taken his second medical degree. In 1811-12 Dr Sewall attended the Harvard Medical School and received the degree of doctor of medicine. In the year of his graduation he became a member of the Massachusetts Medical Society. He returned to his practice at Chebacco, where he served as preceptor for students. In 1813 Dr Sewall married an older sister of Rufus Choate, later famous at the Massachusetts bar.<sup>28</sup>

Immediately after his conviction Dr Sewall went to Washington, District of Columbia, far enough away so that the story of the resurrections at Chebacco would not be commonly known. At that time there was neither an arts nor a medical college in Washington. In 1821 Columbian College was organized, and in 1822 it began instruction in arts. Its plans included a medical school to be known as the National Medical College. In 1821 Dr Sewall was elected professor of anatomy in Columbian College.<sup>29</sup> At that time he had been in Washington less than two years, and had had no experience in medical teaching except as preceptor to students at Chebacco.\* One may infer that Dr Sewall's extensive study of

practical anatomy, and probably the teaching of it to his private students in Chebacco in the winter of 1818 had prepared him to accept such a professorship. He was the only professor of a medical subject appointed at that time. For four years he worked on the establishment of a medical college, and in March, 1825, this was opened under the name of the National Medical College, Medical Department of Columbian College, which soon took rank with the best American medical schools. Dr Sewall was truly its founder, and became its dean, holding this office for nineteen years. In the early years of his incumbency he was professor of anatomy and physiology, later professor of medicine.

The address which Dr Sewall delivered at the opening of this school was devoted to a review of medical education in the United States up to that time, and was the first comprehensive treatise of the subject, prior writers on medical education in this country having confined themselves to one or two institutions. The paper, which includes descriptions of medical schools and medical educators and some statistics, is the pioneer item in this country on the subject.<sup>29</sup> When Dr Thacher, three years later, published his *American Medical Biography*,<sup>3</sup> he included in the introduction a résumé of American medical schools much of which is taken from Dr Sewall's address.

Dr Sewall had a large and select practice in Washington. He wrote and published on several subjects besides medicine. He was considered an excellent teacher and administrator in medical education and a distinguished physician. He was an early advocate of national medical organization, but died April 11, 1845, at the age of forty-nine, a year before the American Medical Association was founded.<sup>28</sup>

It was as an indirect result of the resurrections in Chebacco Parish that a country doctor moved to the national capital, became its leading physician, founded the first medical school in that city and rose to national prominence in American medicine and medical education. It is an "ill wind that turns none to good."

Another series of events related to dissection had an indirect connection with the episode at Chebacco. In the *Essex Register* of Salem of May 9, 1818, appeared an editorial which began as follows:

The great alarm at Chebacco has made the subject of disturbing the dead a very serious concern. Something must be done to render the public mind quiet on the subject. Few who regard the living will be disposed to deny that the human system should be understood. To put beyond doubt the sufficiency of means and yet the safety of common graves the government must prevent the temptations to violate them

\* It is possible that Dr Sewall was demonstrator of anatomy at the Harvard Medical School following his graduation but the available records of that period do not name the demonstrators of anatomy.

the laity called grave robbing or body snatching, but which those members of the medical profession versed in more elegant language termed "private resurrection." Attacks by mobs were not frequent, but search of a medical school by a sheriff was a frequent event. These searches were usually without result, since every medical school had a place of concealment for the few cadavers which it might have on hand—few because cadavers were difficult to obtain, and because, when obtained, dissection was rapidly completed by a small group of students and the skeleton was removed. One place of concealment was the cupola, an architectural feature of many early medical school buildings, not only ornamental but useful. By block and tackle several cadavers could be quickly hoisted into the cupola through a trap door, whereupon the ladder by which the cupola had been reached could be hidden between the partitions of the building.

The arrest of medical students, often including the demonstrator of anatomy, for suspected participation in resurrections was a common occurrence, but the records of conviction are few, and the penalty rarely exceeded a small fine.

We shall now return to Ipswich, where Dr. Firmin "made his anatomy." On the night of January 10, 1818, lights were seen in the hillside graveyard of Chebacco Parish.<sup>26</sup> A diary, written in a neighboring town, shows that six inches of snow fell that night. A snowstorm was a necessary adjunct of resurrection in winter if there was any snow on the ground, since only by falling snow were tracks obliterated. The lights visible on the hillside must have been due to faulty technique, since lanterns used at resurrections were usually carefully shaded. It was suspected that the grave of Sally Andrews, who had died on Christmas Day, had been disturbed. When spring came and the snow disappeared her grave was opened and found empty. Then suspicion arose that more than one grave had been disturbed, so all the graves of burials of that winter were opened and eight coffins were found empty. In April the papers of Salem, the county seat twelve miles distant, carried the result.<sup>21 22</sup> Newspaper accounts are abbreviated in a history<sup>23</sup> of the town written sixteen years later, as follows:

Exhumation of the Dead. April 17, 1818. Great excitement prevails in Chebacco because it was discovered that no less than eight bodies have been taken from their graveyard. They adopt methods for detecting the person or persons concerned in the act. July 23 Mr. Crowell preaches at the request of his people an interesting sermon on the occasion from John xx 13. The individual who was found to have disinterred these bodies for anatomical purposes was largely fined.

A record<sup>25</sup> in another place shows that the eight people included three men, two women, two boys and a negro servant.

At a parish meeting held on April 17 a committee was appointed to raise money as a reward "for discovering the author or authors of the late horrid deed." At a meeting on April 21 there is reference to "the empty coffins now lying exposed to public view" and to the appointing "of a day for the solemn reentering of said coffins in one grave in some conspicuous part of the burying ground" and "that a monument be erected over them by subscription with the names of the deceased whose bodies were stolen inscribed there on to perpetuate the memory of the horrid deed."<sup>24</sup>

An advertisement dated April 25 offering \$500 reward for information first appeared in the Salem papers on April 28. Its last appearance was on May 12, which probably indicates the approximate date of detection of the offender.<sup>21 22</sup> This advertisement was signed by three prominent citizens of the parish. A search of their genealogies shows that each of the three was either a parent, a brother or a son of one of those whose bodies were taken. The eight empty coffins, which had been "exposed to public view" for over three months, were buried in a common grave on July 23, but on account of failure to secure funds the proposed monument was not erected. On this occasion Mr. Crowell preached a sermon which, as published, contains over twelve thousand words.<sup>25</sup>

Mr. Crowell's sermon has points of interest besides its length. He said that dissection in itself was not unchristian. This was not in accord with popular belief linking dissection and crime. Inferentially he advocated a law that, in order to protect private graves, would bestow the bodies of all criminals, not merely those of duelists and murderers, for anatomical study. Furthermore, he presented a series of arguments of those who defend private resurrection for anatomical study, and examined each. This résumé, probably derived from a physician, is of interest as giving the attitude of the medical profession at that time.<sup>26</sup>

In the Supreme Judicial Court, sitting in Salem in November, 1818, the jury returned three separate indictments, each involving a different body, against Dr. Thomas Sewall, the local physician in Chebacco. On the plea of counsel that one indictment was inaccurately drawn, it was not pressed.<sup>26</sup> The two other indictments were continued to the April term of 1819, and again to the November term. Dr. Sewall was tried in Novem-

## THE CEREBROSPINAL FLUID IN OPTIC NEURITIS, "TOXIC AMBLYOPIA" AND TUMORS PRODUCING CENTRAL SCOTOMAS\*

ARTHUR L. WATKINS, M.D.†

BOSTON

THE differential diagnosis of visual disturbances, particularly those with a central scotoma of the visual field caused by tumors or abscesses, and toxic or degenerative conditions, has been a subject of numerous publications<sup>1-6</sup> There still remains difficulty, however, in separating cases requiring surgical treatment, as recent experiences in this clinic have demonstrated. Some patients have been operated on with negative findings, while others have been operated on too late to benefit sight. In an attempt to add to our better understanding of this problem, 120 patients have been studied who came to the hospital primarily for loss of vision and were found to have central scotomas. All the patients received one or more

lumbar punctures,† and to present the results of these examinations is the purpose of this study. In spite of the voluminous literature on cerebrospinal fluid and the recent publication of a book devoted to the subject, little information is available beyond individual case reports as to the cerebrospinal fluid findings in affections of the optic nerves.

The classification of the various groups of disorders affecting the optic nerves, chiasm and tracts has been and still is confusing. It is necessary, therefore, to make arbitrary definitions for the sake of clarity. In the first place, all patients with syphilis have been excluded, and in this series blood Wassermann and Hinton tests and spinal-fluid Wassermann tests were all negative. There remain the following groups: retrobulbar optic neuritis, "toxic amblyopia", other types of optic neuritis, and tumors.

‡All fluids were examined with the same technique in the Spinal Fluid Laboratory of the Massachusetts General Hospital.

by providing proper subjects for the Anatomist and Physician. They may be found among those who have forfeited their lives and liberties to the people.

In continuation the medical profession is called upon to secure enactment of such a law<sup>21</sup>

There was no law in any New England state at this time regarding the bodies of convicts other than murderers. The first came in Connecticut in 1824. This advocacy, from a lay source, of legalization of practical anatomy was unusual, and may have been inspired by a young physician who had located in Salem a few weeks before and who later became the leading surgeon of that city. This was Abel Lawrence Peirson, a graduate in 1816 from the Harvard Medical School, to which he sent many students in later years.

The editorial just quoted had no immediate effect on the Massachusetts Medical Society. Examination of its records shows no mention of dissection for ten years. In 1828 this society revised its recommended program of study for one seeking membership, and added this significant sentence: "It is recommended as indispensable for a practitioner of Medicine and Surgery to prosecute dissection." This advised what, under the law of 1815, was a felony. The situation needed to be remedied.

Dr. Peirson became a fellow of the Massachusetts Medical Society in 1821. In 1826, while still a very young man, he was elected a councilor. In February, 1829, he proposed that a committee be appointed to petition the legislature "to modify the existing laws which operate to forbid the procuring of subjects for anatomical dissection." In June the society made Dr. Peirson chairman of a committee of nine chosen for this purpose. The committee included the most eminent members of the society, all of them much older than Dr. Peirson.<sup>30</sup>

This committee prepared an address to the public which advocated that bodies which must be buried at public expense be made available for practical anatomy. A considerable part of the address was devoted to an argument against the traditional idea that dissection was a stigma and a penal offense. Some passages clearly refer to the events at Chebacco and the conviction of Dr. Sewall, although no names are mentioned. Much of the phraseology of the Salem editorial of 1818 is included verbatim.<sup>4</sup> Here and elsewhere are hints that Dr. Peirson was more intimately connected with the events at Chebacco than appears from the records so far discovered.

In his address to the legislature in 1830 the Governor commended the request of the medical profession for change in the law regarding dissection.<sup>31</sup> A bill was introduced at the end of the

session and carried over to the session of 1831, when it came up early in February. On invitation, Dr. John C. Warren delivered a lecture on anatomy at a joint session of the legislature. The bill was enacted and signed February 28, 1831. Its title was "An Act more effectually to protect the Sepulchres of the Dead and to legalize the study of Anatomy in certain Cases,"<sup>32</sup> a name which subordinated the main purpose of the law. In his address in 1830 the Governor had cautioned that because of the state of the public mind, any law on this subject should be drawn without too direct reference to its purpose. The law was slightly amended in 1834 and the new bill was signed April 1. On July 5 the legislature of New Hampshire passed an identical law.<sup>33</sup>

The most important feature of this act was that it repealed that part of the statute of 1815 which made it a felony to be in possession of any human body to be used for dissection, except that of a duelist or an executed murderer. A second important feature was that it began to remove from the public mind the old idea that dissection was necessarily linked with major crimes and therefore a stigma, but this notion persisted, and thirty years later Thomas Wentworth Higginson referred to "the last ignominy of the dissecting room."<sup>34</sup>

This law did not provide adequate dissecting material for the medical schools, although in its text it gave them preference. This was because the turning over to medical schools, licensed physicians or medical students of bodies that must otherwise be buried at public expense was permissible, but not compulsory upon public officials, and local and personal sentiment deterred such officials from the permissive course. Private resurrection, mainly from potters' fields, continued.

This law was the beginning of the present-day anatomical laws in New England. Dr. Peirson of Salem was the leader in securing its enactment, and there is definite relation in time and place between the events in Chebacco in 1818, leading to the conviction of Dr. Sewall, and the activity of Dr. Peirson, who located in Salem in the midst of the excitement caused by these events and remained there until his death in 1853. The causal relation cannot, with evidence so far discovered, be proved intimate, but the sequence, location and proponent of the law suggest at least an influence. Thus the episode of 1818 is seemingly related to the present-day teaching of anatomy in New England.

## THE CEREBROSPINAL FLUID IN OPTIC NEURITIS, "TOXIC AMBLYOPIA" AND TUMORS PRODUCING CENTRAL SCOTOMAS\*

ARTHUR L. WATKINS, M.D.†

BOSTON

THE differential diagnosis of visual disturbances, particularly those with a central scotoma of the visual field caused by tumors or abscesses, and toxic or degenerative conditions, has been a subject of numerous publications<sup>1-6</sup>. There still remains difficulty, however, in separating cases requiring surgical treatment, as recent experiences in this clinic have demonstrated. Some patients have been operated on with negative findings, while others have been operated on too late to benefit sight. In an attempt to add to our better understanding of this problem, 120 patients have been studied who came to the hospital primarily for loss of vision and were found to have central scotomas. All the patients received one or more

lumbar punctures,† and to present the results of these examinations is the purpose of this study. In spite of the voluminous literature on cerebrospinal fluid and the recent publication of a book devoted to the subject, little information is available beyond individual case reports as to the cerebrospinal fluid findings in affections of the optic nerves.

The classification of the various groups of disorders affecting the optic nerves, chiasm and tracts has been and still is confusing. It is necessary, therefore, to make arbitrary definitions for the sake of clarity. In the first place, all patients with syphilis have been excluded, and in this series blood Wassermann and Hinton tests and spinal fluid Wassermann tests were all negative. There remain the following groups: retrobulbar optic neuritis, "toxic amblyopia", other types of optic neuritis, and tumors.

\*All fluids were examined with the same technique in the Spinal Fluid Laboratory of the Massachusetts General Hospital.

From the Massachusetts General Hospital and the Massachusetts Eye and Ear Infirmary.

†Assistant in neurology, Harvard Medical School; resident in neurology, Massachusetts General Hospital.

## RETROBULBAR OPTIC NEURITIS

The retrobulbar cases are further divided into acute and chronic, depending on the speed of onset. This group was characterized by a rapid loss of vision within a few hours or days in acute cases, and gradual loss of vision in a month or more in the chronic cases. There was usually tenderness of the eyeballs, either choked, pallid or normal optic disks, and visual fields with central scotomas. There were 40 cases of acute retrobulbar neuritis, with an average age of thirty-three, 85 per cent being under forty. Loss of vision progressed rapidly over a period of a few hours or days. Sixty per cent of the patients complained of painful eyes or pain on motion of the eyeballs. The optic disks showed hyperemia or slight choking in 48 per cent, and in the other cases were negative or slightly

multiple sclerosis before, coincident with or after their visual disturbances. If, however, only the 18 cases are considered which were followed for more than three years, the incidence rises to 50 per cent. The follow-up, however, was not sufficient to rule out multiple sclerosis in the cases of unknown etiology. Seven out of the 9 cases with multiple sclerosis were unilateral, and 5 of these had strong first-zone gold-sol curves. Of the 9 cases associated with multiple sclerosis, in 3 the retrobulbar optic neuritis occurred two, six and fourteen years after the first symptoms, in 3 the retrobulbar neuritis preceded the multiple sclerosis by four, three and one years, and in 3 the retrobulbar neuritis and other symptoms were noted coincidentally.

We conclude, therefore, from our examination

Table 1 Summary of Data in 120 Patients with a Chief Complaint of Loss of Vision

DATA	DIAGNOSIS			
	ACUTE RETROBULBAR OPTIC NEURITIS (40 CASES)	CHRONIC RETROBULBAR OPTIC NEURITIS (39 CASES)	TOXIC AMBLYOPIA (30 CASES)	TUMORS (11 CASES)
Age	Avg 33 85% under 40	Avg 39 62% over 40	Avg 52 54% over 50	Range 24 to 59
Clinical findings				
Tender eyeballs	60%	22%	None	None
Optic disks	48% choked 12% pale 40% negative	21% choked 72% pale 7% negative	100% negative or slightly pale	1 choked 7 pale 3 negative
Visual field defects	Central scotoma	Central scotoma	Central or cecocentral scotoma	8 central scotoma 3 probable scotoma
Spinal fluid findings				
Initial pressure	60 to 300 mm	80 to 200 mm	80 to 210 mm	110 to 420 mm
Cells	95% normal (0 to 34 lymphocytes)	100% normal	70% normal (0 to 13 lymphocytes)	10 normal (0 to 50 lymphocytes)
Total protein	Avg 34 mg (19 to 49 mg)	Avg 35 mg (15 to 49 mg)	Avg 33 mg (20 to 70 mg)	Avg 101 mg (56 to 147 mg)
Gold sol curve	28% positive	100% negative	100% negative	1 positive
Course	88% better 18% recurrence	100% unimproved	40% better	All gradually or rapidly grew worse until time of operation

pale. Central scotomas were of varying character and degree. The visual acuity varied from 20/30 to complete loss of light perception. In 75 per cent of the patients only one eye was involved. Although 88 per cent recovered from the acute attack, 18 per cent had recurrences in the same or the opposite eye.

The cerebrospinal fluid initial pressure was normal, or in a few cases increased. The cellular content was normal in 95 per cent, there being only 2 cases with 19 and 34 lymphocytes per cubic millimeter respectively. The total protein was also normal, averaging 34 mg per cent and varying from 19 to 49 mg per cent. Twenty-eight per cent of the 40 cases had an abnormal gold-sol curve, that is with 3's or 4's or 5's in the first zone or rarely in the mid-zone.

Twenty-seven per cent of these patients had

of 40 cases of acute retrobulbar neuritis that the cerebrospinal fluid is normal except in cases caused by multiple sclerosis. In these, which form 25 to 50 per cent of the group, the gold-sol curve may show a strong first-zone reaction.

Thirty-nine cases were classified as chronic retrobulbar optic neuritis. The onset of the visual disturbance in these patients was slow, and gradually progressive over a period of months rather than weeks. The average age was somewhat higher than in the acute cases, being thirty-nine, with 62 per cent over forty. Both eyes were affected slightly more frequently (54 per cent) than one alone, and the eyeballs were tender and painful in only 22 per cent. Pallor of the optic disks was usually observed (72 per cent), but they were hyperemic in 21 per cent and normal in 7 per cent. The characteristic field was a central scotoma, and the visual impairment showed progression to

nearly complete blindness. Lumbar punctures revealed no abnormality in initial pressure, cellular content, total protein or gold-sol curve. The total protein averaged 35 mg per cent, and upper and lower limits were 49 and 15 mg per cent.

The etiology was unknown in 85 per cent of the cases and proved to be multiple sclerosis in 15 per cent. Because of uncertainty in diagnosis there were 2 exploratory operations among this number, both revealing no gross lesions of the optic nerves, chiasm or sheaths. Although no pathologic material is available the presence of tumors in this group is unlikely in view of the long time (three to twenty years) most of these cases were followed without roentgenologic changes or the development of other symptoms or signs. The course in this group is significant, for in no case was there any improvement in vision in spite of various treatments, including general hygienic measures, spinal-fluid drainage, search for and, if present, eradication of foci of infection, and fever therapy with typhoid vaccine. It is probable that a certain number of these cases might be classified as Leber's disease, but because of no definite hereditary background they were not so diagnosed. The cerebrospinal fluid has been reported as normal in this condition, and one expects a normal fluid in chronic retrobulbar neuritis also, as concluded from our series.

#### "TOXIC AMBLYOPIA"

"Toxic amblyopia" was diagnosed in 30 cases, the average age being fifty-two, a distinctly older age incidence. The course was one of slow progressive loss of vision in both eyes, although not necessarily equally. There was one exception, a case of acute lead intoxication in which the onset was abrupt within twenty-four hours. The eyeballs were in no case tender, and the optic disks were either normal or slightly pale. The diagnosis was made from visual-field examination, the characteristic field being a cecocentral scotoma, particularly for red and green, although in some cases it was made from a history of over indulgence in alcohol and tobacco and the presence of a central scotoma similar to retrobulbar neuritis. Most of the cases were diagnosed in the Massachusetts Eye and Ear Infirmary on these characteristic clinical findings, before there developed more recent knowledge concerning the role of avitaminosis. The term "toxic" is therefore somewhat misleading, although there is still no general agreement as to the role of possible toxic agents, particularly tobacco and alcohol. Forty per cent of these patients improved after reducing or stopping the use of tobacco or alcohol.

Cerebrospinal fluid examinations showed in-

ital pressures which were usually normal (80 to 210 mm of water). In general there was no pleocytosis, although 1 case showed 13 lymphocytes. The total protein averaged 33 mg per cent, being distinctly abnormal in only 2 cases, the highest being 70 mg per cent. No explanation is apparent for the abnormality in these 2 cases, as they clinically resembled the others. The gold-sol curve was negative in all cases. In summary, then, a normal cerebrospinal fluid was found in over 90 per cent of patients with "toxic amblyopia."

#### OTHER TYPES OF OPTIC NEURITIS

This group includes those cases which showed a diminution of vision, papillitis and a constricted field of vision. The classification is purely arbitrary, for it is well realized that the term "optic neuritis" is so widely used, to include almost any affection of the optic nerve, that it must be defined in each separate usage. It is possible that in these cases inasmuch as there was loss of vision there actually were relative central scotomas, although not demonstrated, and the relation between these cases and retrobulbar neuritis is certainly close. They are separated only because the fields of vision differed from the others and loss of visual acuity was less marked than in the typical case of retrobulbar neuritis. The 5 cases included in this study were between the ages of four and forty-six. There was tenderness of the eyeball in only 1 case. As already mentioned, there was slight choking of the optic disks and peripheral constriction of the visual fields, and half had unilateral involvement only. Lumbar punctures showed normal initial pressures, 0 to 10 lymphocytes, normal total protein and negative gold-sol curves. All cases were of fairly rapid onset during the course of a few days, and normal vision was regained. In 2 cases there occurred a pansinusitis coincidentally, and in another, hay fever. One patient had a definite lead intoxication which seemed of etiologic significance.

Six other cases are of interest because of optic neuritis, although it was not the chief complaint. Three patients had transverse spinal cord lesions and retrobulbar neuritis, which was thought to be on an unclassified infectious basis but fitted into the clinical syndrome of neuromyelitis optica. The other 3 were cases of blindness with central scotomas and multiple peripheral neuritis. An autopsy of one of the latter cases revealed extensive periarteritis. In the 3 cases of neuromyelitis optica and the 2 of multiple peripheral neuritis with optic neuritis there was definite abnormality of the cerebrospinal fluid, with 10 to 30 lymphocytes and a total protein as high as 585 mg per cent. In the case of periarteritis the fluid was normal.

## TUMORS

There were 11 patients studied who came to the hospital primarily for loss of vision without other appreciable symptoms, and who were found to have tumors pressing on the optic nerves, chiasm or tracts, at operation or autopsy. These cases are of particular interest because at first the diagnosis of retrobulbar neuritis or "toxic amblyopia" was made. In 8 of these definite central scotomas were found, and in 3 the loss of vision was so extensive that accurate determinations of visual fields were impossible. The optic disks were atrophied in 7 cases, choking in 1, and normal in 3. In no case were the eyeballs tender or painful on motion. The visual loss was bilateral in 9 patients. Stereoscopic x-ray examination of the skull without air injection suggested tumor in the region of the sella turcica in 5 cases and was negative in 6.

Examination of the cerebrospinal fluid by lumbar puncture revealed initial pressures which were normal in 7 cases and slightly elevated, about 200 mm of water, in 4. The cellular content was normal in all but 1, which showed 50 lymphocytes. The total protein averaged 101 mg per cent, being abnormally high (greater than 50 mg per cent) in all cases. Two gold-sol curves had mild mid-zone reactions, the others were negative. This fluid abnormality of elevated protein content was of clinical value for correct diagnosis and operation, except in 1 case of aneurysm in which the diagnosis was not made until post-mortem examination. The pathological reports in these 11 cases were: 3 pituitary tumors, 7 meningiomas and 1 aneurysm of the circle of Willis, all these caused pressure on the optic nerves.

For comparison 11 cases are included which had similar histories with complaints of visual loss only. On first examination the diagnosis of retrobulbar neuritis was entertained, but on visual-field determination a bi-temporal or homonymous hemianopsia was discovered which was sufficient to localize the lesion in the optic chiasm and to suggest tumor. In 8 cases with bi-temporal field defects the optic disks were normal in 5 and atrophied in 3, while in 1 there was atrophy of one eye and choking of the other. Three cases with homonymous hemianopsia had primary optic atrophy. X-rays of the skull were negative in 4 cases and showed evidence for tumor in the pituitary region in 7.

The initial spinal fluid pressure was normal in 10 cases and elevated in 1. Cell counts were normal in all except 1, which had 21 lymphocytes. The gold-sol curves were also negative. The total protein averaged 60 mg per cent but was normal in 4 cases. The pathological findings upon oper-

ation or at autopsy included meningioma, pituitary tumor, craniopharyngioma and aneurysm, all pressing on the optic chiasm.

The conclusion is made from the 22 tumor cases that the cerebrospinal-fluid pressure, cellular content and gold-sol curve may all frequently be within normal limits, but the total protein is usually increased two to five times normal when there is present a central scotoma from pressure of tumors or aneurysms on the optic nerves or chiasm.

## COMMENT

The literature on retrobulbar neuritis was summarized by Dunphy<sup>8</sup> in 1930, and very little of importance has been added since then. The relation between multiple sclerosis and retrobulbar neuritis has been well recognized. There are available no long series of cases of statistical value, but authors agree fairly closely. When the cases of Adie<sup>3</sup> and Popek<sup>9</sup> and those reviewed by Dunphy<sup>8</sup> are combined, we find 402 cases of retrobulbar neuritis, 160 (40 per cent) having multiple sclerosis.

Several papers have been written on the relation of sinus infection to retrobulbar optic neuritis,<sup>10</sup> but in recent years this etiology has been belittled, in the present series, sinus infection was sought in each case but was found in only 1. There remain about half the cases in which no satisfactory etiologic agent could be determined. Clinically the important point in diagnosis is the mode of onset and course of the disease. The acute cases nearly all improve spontaneously, and do so before the diagnosis of tumor need be seriously entertained. They occur in a young age group, and are largely unilateral and associated with tender, painful eyeballs. The cases of chronic retrobulbar neuritis offer a difficulty in differentiation from tumor, since their courses are not dissimilar and the prognosis for spontaneous recovery is poor. It is in this group particularly that spinal-fluid examination may be of great value in leading one to the correct diagnosis.

The etiology of "toxic amblyopia" is beyond the scope of this paper. Clinically the diagnosis is not usually difficult. It occurs in a distinctly older age group, characteristic field defects are present, and in general the cerebrospinal fluid is normal, although there may be some abnormality. Carroll<sup>4</sup> in 1935 reported 10 cases with cerebrospinal-fluid examinations. 9 had normal cell counts, in 6 the total protein was greater than 40 mg per cent and in 2 greater than 60 mg. In 90 per cent of the cases in the present series, however, the fluid was normal, and clinically an increased total protein was found of distinct value in changing

the diagnosis from "toxic amblyopia" to tumor and in subsequent operative improvement

The small group of cases classified as optic neuritis offered little difficulty in differentiation from tumor, as the course was benign with fairly rapid recovery, and other etiologic factors were usually apparent. Normal pressures help to differentiate the disease and papilledema.

The cases with tumor are of particular interest because of the importance of making the diagnosis so that sight might be saved. Bi-temporal or homonymous field defects were of the utmost diagnostic value, and led one to suspect tumor, very often x-ray changes bore out this assumption. There are a certain number of cases in which the fields may be similar to those of retrobulbar neuritis of other origin, as noted by Kennedy,<sup>1</sup> and it is in these cases in particular that the spinal-fluid protein may be of differential significance. No conclusions can be drawn as to why some tumors produce central scotoma and others temporal or homonymous field defects, as the anatomical descriptions are not minute enough. It can be seen, however, that pituitary tumors, meningiomas and aneurysms can all produce a central scotoma, and the presence of this defect does not therefore help in pathological differentiation.

Chiasmal arachnoiditis has been mentioned in the literature by several authors as a cause of blindness, and is said to produce various defects in the visual fields. In particular, Craig and Lillic<sup>5</sup> cited 8 cases, 3 of them with necropsy reports which showed generalized inflammatory reactions of the meninges. Clinically they were associated with infection such as encephalitis or trauma. As indicated, 3 patients died after operation, and the others were not helped by the procedure. Usually the diagnosis of arachnoiditis has been made on a basis of a negative operation or the finding of thick-

ened chiasmal arachnoid, and in these cases the results have been more favorable.<sup>6</sup> In no case in this series has a diagnosis of chiasmatic arachnoiditis been confirmed.

#### SUMMARY AND CONCLUSIONS

The cerebrospinal-fluid findings in 120 cases of acute and chronic retrobulbar neuritis, "toxic amblyopia" and tumors producing central scotomas are reported.

In acute retrobulbar neuritis without demonstrable cause the spinal fluid was normal except in older cases associated with known multiple sclerosis (25 to 50 per cent). In these there were a few lymphocytes, a high normal total protein and a strong first-zone gold-sol reaction.

The spinal fluid was normal in so-called chronic retrobulbar neuritis and probable "toxic amblyopia" in 95 per cent of the cases.

In 11 patients with tumor or aneurysms producing central scotomas the spinal-fluid protein was increased two to five times the normal amount. This fluid abnormality was a valuable diagnostic point in differentiating tumor and the other causes of central scotomas.

## REGIONAL ENTERITIS

## A Study of Five Cases

WILLIAM A R CHAPIN, MD \*

SPRINGFIELD

IN 1932 Crohn and his associates<sup>5</sup> described regional enteritis and its treatment. Since that time over thirty articles have appeared in the American literature dealing with this condition. It was originally described as terminal ileitis, later as regional ileitis<sup>4</sup> and regional enteritis,<sup>1</sup> and more recently as segmental enteritis,<sup>12</sup> the terminology having been changed with increasing knowledge of the disease.

In the first described cases only the terminal ileum was involved. Later the disease was observed more proximally in the small intestine extending up to the jejunum,<sup>8</sup> and it has been found in the stomach<sup>10</sup> and large bowel.<sup>6, 12</sup> It was originally thought to be a condition confined to young adults, but the incidence is now known to be much broader, with an average age of thirty-two. More men than women are affected.

The etiology of the disease is generally admitted to be unknown.<sup>9</sup> Half Crohn's patients had had appendectomy. In discussing Crohn's<sup>9</sup> paper Felsen quoted several cases of his own which he believed to be due to bacillary dysentery. But Crohn in reply stated that in his series of 60 cases only 1 had a positive agglutination test for dysentery, and that when many cases of dysentery were in the hospital there were no patients with regional ileitis. Paulson,<sup>15</sup> on the other hand, agrees with Felsen as to the bacillary origin of the condition.

In the American literature the majority of cases of regional ileitis seem to be in the Jewish race, and it is noteworthy that persons of Irish descent or those with old American names are scarcely ever affected with the disease. Inasmuch as 70 per cent of the population of New England have so-called Irish or Yankee names, it would be expected that some such proportion of cases with this condition would bear such names were there no racial predilection. This is, however, not so in the 5 cases reported in this paper. In this regard, Dr Crohn writes

Your question as to a racial tendency in regional enteritis is one which has repeatedly been asked of me. I doubt very much that enteritis is in any way a racial or geographic problem. The world literature on ileitis now covers almost all countries. England seems to be having a great number of cases, particularly Scotland. Holland also seems to have a large number

of cases due to the fact that Snapper and his clinic are very alert on the subject.

Jews are clannish people and have a tendency to congregate. Both my practice and the patients in the hospital are predominately Jewish, and therefore most of our cases are of Jewish extraction. Lewisohn,<sup>17</sup> of New York City, does not believe we are dealing with a racial disease. Two of Probstein's<sup>18</sup> 3 patients were Jewish.

Homans<sup>9</sup> reported 2 cases which occurred in Jewish patients, and he<sup>10</sup> writes that he thinks that in Boston he has seen no one suffering from this disease who was not a Jew. Clute<sup>2</sup> did not stress the racial strain of his 2 cases. He<sup>3</sup> writes that he has recently operated on another case in an Italian woman. Mixer and Starr<sup>13</sup> reported that 17 of the 20 patients observed at the Beth Israel Hospital, Boston, were Jewish. Dr Mixer<sup>14</sup> writes "In a survey of the literature of the subject it seems to be generally accepted that there is a marked preponderance of regional enteritis occurring among Jews. We have had no outstanding number of Irish." Of the 5 cases reported in this paper, 3 patients were of Polish, Italian or French extraction.

Bearing in mind that although thromboangitis obliterans has now been shown not to be a race-linked disease, there is certainly something to arrest one's attention in the apparent racial distribution of the disease under consideration.

The symptomatology of the disease is most varied, and may be atypical in any particular case. In general the cardinal symptoms and signs are pain in the right lower quadrant, often colicky, fever, loss of weight, leukocytosis, marked anemia and a palpable mass in the abdomen. Any of these may be lacking. Crohn<sup>5</sup> speaks of four distinct clinical groups: first, those associated with peritoneal inflammation in a localized portion of the abdominal cavity, secondly, those simulating ulcerative colitis or enteritis, thirdly, those with obstructive symptoms, and fourthly, those attended by the formation of fistulas. Pessagno<sup>16</sup> has presented a case in which all these phases existed.

Not uncommonly the disease simulates acute appendicitis.<sup>11</sup> Undoubtedly it has been overlooked in many cases in which a normal appendix has been removed through a small appendectomy wound, and in the absence of a pathological examination it is quite probable that many "tumors" actually due to regional enteritis have been removed.

and an operative diagnosis of cancer made. In recent years the barium enema and barium meal, which in regional ileitis demonstrate a thin, string-like shadow, have been of great service in the clinical diagnosis of the condition.

The nature of the pathologic lesion is in doubt. It is more than probable that the condition has at its basis several histologic pictures. Crohn and his associates<sup>5</sup> believed that it was characterized by a subacute or chronic necrotizing and cicatrizing inflammation, the ulceration being subordinate to the connective tissue reaction and in the walls of the intestine leading to stenosis or more rarely

Figure 1

*There is a small depression in the region of the ileocecal valve. The terminal loops of ileum have filled irregularly and the most terminal portion has not retained the barium.*

to multiple fistulas. In gross, these observers described the disease as resembling tuberculosis, and they were of the opinion that the giant cells seen on microscopic sections were not diagnostic, but rather were due to vegetable matter caught in the ulcerated areas.

Homans<sup>2</sup> described lesions simulating Boeck's sarcoid rather than tuberculosis, he believed that the giant cells were produced in reaction to a foreign body, perhaps a lipid. Clute<sup>2</sup> pointed out that regional enteritis involved the mesentery as well as the wall of the bowel, and was of the opinion that the condition might start in the local lymph nodes. Lewisohn<sup>12</sup> in 1938 predicted that regional enteritis might turn out to be only a manifestation of ulcerative colitis, and stressed the importance of recognizing that segments of the intestine which are separated by healthy tissue are

frequently involved. Crohn<sup>6</sup> had previously declared that "skip areas" of this disease must be constantly watched for. Phillips<sup>17</sup> in 1934 reported in some detail the microscopic appearance of the lesion.

In Crohn's<sup>5</sup> first article he recommended excision of the diseased areas. Since then, however, some observers have reported favorable results and apparent cures from sidetracking operations, but since the disease was recognized as an entity only six years ago it is too early to appraise ultimate results. Other surgeons believe that short-circuiting should be done merely as a preparation for subsequent reaction. Even so, operative interference is not unattended by risk, for sinus formation may occur, and every hollow organ of the lower abdomen except the urinary bladder has been reported as having had a sinus connection with the original lesion. These fistulas may be cured by appropriate resection. Homans and Hass,<sup>9</sup> while recommending anastomosis and subsequent resection, declare that operation is by no means a certain cure and that there may be spontaneous recovery.

#### CASE REPORTS

*Case 1* (S. H. 128,926) H. J. P., a 53-year-old salesman, was admitted to the Springfield Hospital May 11, 1937, with irregular dietary habits and a colicky pain in his abdomen. He did not take alcohol. During the previous year he had noticed intermittent spasms of pain in the abdomen, at times localized in the right side, and accompanied by difficulty in bowel movements, but no bleeding. He had lost 30 pounds in weight during the year. The past history was non-contributory.

Physical examination showed a worried and somewhat emaciated man whose general appearance indicated an acute surgical condition in the abdomen. A barium enema given on the 1st hospital day showed an apparently complete obstruction about 5 cm. above the ileocecal valve. Under the fluoroscope the same defect was demonstrated, and the x-ray report was as follows: "The enema passed rapidly to the region of the cecum, with all parts movable. This has the appearance of a new growth."

Laboratory studies revealed a normal urine, a hemoglobin of 95 per cent and a red-cell count of 4,900,000. The white-cell count was 10,700, with 76 per cent polymorphonuclears, 11 per cent lymphocytes, 2 per cent eosinophils and 1 per cent myelocytes. Slight achromia was present, and the platelets were normal. The blood pressure was 154/76, the heart was slightly irregular, both in rate and rhythm. The lungs were clear and resonant, the extremities were normal, and the abdomen was normal except for some tenderness in the right lower quadrant.

With a preoperative diagnosis of malignancy of the bowel, operation was performed on May 13 with nitrous oxide oxygen and ether anesthesia, under which the patient did poorly. A right rectus incision was used. A thickened constricted tumor involving the cecum and adjacent small and large bowel was found. Palpation of the liver and mesentery showed no enlarged lymph nodes. About 30 cm. proximal to the cecum, the ileum was brought up through a midline incision, an ileostomy tube sewed in, and the peritoneum sewed only underneath the

intestine. The original wound was closed in layers. The next day the patient developed bronchopneumonia.

On May 27, under avertin, nitrous oxide, oxygen and ether anesthesia, a Mikulicz colostomy with resection of the tumor was accomplished. The pathological report was as follows:

The capillaries of the mucosa are distended with red blood cells, and in the stroma are found a few polymorphonuclear leukocytes, eosinophils and plasma cells. The blood vessels in the submucosa are dilated and filled with red blood cells and the tissue in this area shows some edema. There are numerous lymphocytes, polymorphonuclear leukocytes and eosinophils in this edematous tissue. In the muscularis and involving the submucosa are numerous necrotic areas showing giant-cell formation, with infiltration of a large number of polymorphonuclear leukocytes and plasma cells. This necrosis is not caseous in type. In some of these areas fibroblastic regeneration is marked, causing disappearance of muscle fibers. Connective tissue scarring is a prominent feature. Diagnosis: regional ileitis.

There was another stormy convalescence. The wound edges were very much inflamed and had a digested appearance. The bowel movements were loose, and the skin edges were treated with zinc oxide. Following a low residue diet the movements improved and the wound edges became less inflamed. Shortly the patient was up in a wheel chair and took care of the draining colostomy himself.

On August 6 the colostomy was closed and the patient developed a postoperative atelectasis from which he recovered in 3 days, during which time an oxygen tent was used. The wound improved and gradually healed and the patient was up and about. On August 24 he was discharged to his home with the colostomy wound closed and healed, but with the ileostomy wound still open. On September 22 he returned to the hospital and the ileostomy wound was closed. One Penrose drain was left in, reaching to the fascia. The patient was discharged October 6. Since then he has gained 20 pounds, feels perfectly well and has a clinically sound intestinal tract.

*Comment.* This case was at first wrongly diagnosed. The barium enema was of no help toward a correct pathological diagnosis, and a barium meal would have given him complete obstruction. He had neither a high white-cell nor a low red-cell count. He had no blood in his stools. A Mikulicz operation at first would probably have been fatal. This case demonstrates the necessity of being ready to do a lot or a little, depending on what is found and the patient's condition on the table. The ileostomy saved a life and in no way interfered with later treatment. Until the pathologist made his report, the tumor was thought to be malignant. Without this report and our present-day knowledge, it might have been regarded as a cancer.

*Case 2* (S. H. 131,085). F. F., a 54-year-old woman, was admitted to the hospital September 30, 1937. Her chief complaint was constipation with intermittent pain in her abdomen. For the past several years she had had to take laxatives daily. She had had intermittent black stools and occasional vomiting. The abdominal distress had recently become more persistent. Her appetite was poor and she had lost weight.

The physical examination was negative except for the gastrointestinal tract. The abdomen was generally tender with a feeling of fullness and a possible mass on the right side. On the day of entrance the red-cell count was 4,800,000, the hemoglobin 95 per cent and the white-cell

count 17,000. The following day, with a diagnosis of intestinal obstruction, the abdomen was opened under drop ether anesthesia. A tumor was found that involved the cecum and ascending colon and almost completely obstructed its foramen. A right colectomy was done by the Mikulicz method, staggering the ileum along the colon. A rubber tube was tied into the open end of the ileum, a Page clamp was left on the colon and the abdomen was closed in layers around the protruding ileum and colon. An extensive involvement of the mesenteric lymph nodes was observed, but no nodules could be felt in the liver. The pathological report was as follows:

The section consists of the cecum, appendix, 6 cm. of terminal ileum and 10 cm. of ascending colon. In the cecum is an ulcerated area, 4 cm. in diameter, with slightly raised, firm edges. The crater of this ulceration is dark red and smooth. There is considerable narrowing of the ileocecal valve. Diagnosis: regional ileitis.

On October 13 the red-cell count was 4,170,000, with a hemoglobin of 80 per cent. On October 27 the patient was discharged to her home, but returned on November 3 for the closure of her colostomy stoma. On November 4 the red-cell count was 3,980,000, the white-cell count 12,400 and the hemoglobin 80 per cent. On November 21 a blood examination showed 6400 leukocytes and a red-cell count of 3,650,000. On December 10 the patient was transfused with 420 cc. of whole blood, and 7 days later was discharged from the hospital. Since that time she has been clinically well.

*Comment.* This case illustrates how easily regional ileitis may be mistaken for malignancy with partial obstruction. In this case the white-cell count was raised but the red-cell count was normal, a condition not accounted for by dehydration. On completion of the operation, it was believed that an obstructing malignancy had been removed.

*Case 3* (S. H. 123,951). A. T., a 40-year-old Frenchman, was first seen in April, 1936, with precordial pain. His blood pressure was 180/120. He gave a history of epigastric pain about half an hour after meals. He said that as a young man he had had a rash, and later had received three or four doses of arsphenamine. He denied ever having had a positive Wassermann. He was admitted to the Springfield Hospital on June 10, giving a history of a gradual onset of general abdominal cramps and diarrhea with remissions of a week or less, similar symptoms having been noted 8 or 10 months previously. He said he had lost 22 pounds in the last 3 months. The blood pressure was 175/120, the heart and lungs were essentially normal, the abdomen was normal except for a mass resembling feces just to the right of the umbilicus. The red-cell count was 4,050,000, the hemoglobin 70 per cent and the white-cell count 37,000. The urine was negative. The findings gave the impression of cancer of the lower bowel.

Having developed a slight cold, the patient was sent home to recover from it. He returned on June 14. With a diagnosis of carcinoma he was operated on June 16 and a regional ileitis was found involving the terminal 25 cm. of the ileum, the cecum and all the ascending colon. A Mikulicz resection of the ileum, cecum, ascending colon and hepatic flexure was done. The pathological report was regional ileitis. The ileum and transverse colon were approximated and a Mixer glass tube was stitched into the open end of the ileum. A clamp was left on the colon. The wound was then closed in layers.

On July 2 the redundant colonic spur was amputated by diathermy. On July 23 the colostomy opening was

freed and the mucosa, muscle and fascia were coapted in layers. Two rubber tissue drains were inserted down to the fascia and the skin sutured with silkworm gut. The patient was discharged clinically well on August 12 but died 6 months later from coronary thrombosis.

*Comment* The previous story of abdominal cramps and some diarrhea seemed to justify a preoperative diagnosis of cancer of the lower bowel. In this, as in the two preceding cases, there was no blood in the stools, the red cell count and hemoglobin were a little low and the white-cell count quite high, as one would expect with an ulcerated carcinoma.

At operation, the extent of the condition brought to light the true diagnosis, which was later confirmed by the pathologist.

*Case 4* (S. H. 127,341) A. F., a 22-year-old Pole, was examined January 20, 1937, and the case was diagnosed as recurrent appendicitis. The day before he had begun to have pain in the right lower quadrant and vomited a small amount. He had no headache, no diarrhea, felt a tender mass in his right lower quadrant and gave a history of four or five previous similar attacks which lasted for 4 or 5 days. The history was otherwise negative.

Physical examination revealed a fairly well-developed, rather poorly nourished young man lying quietly in bed but co-operatively alert. The blood pressure was 120/80, with otherwise negative findings except tenderness in the right lower quadrant. The red-cell count was 4,450,000, the hemoglobin 85 per cent and the white-cell count 18,400. The urine was negative.

He was admitted to the hospital, and at operation a markedly inflamed terminal ileum with the distal portion of the appendix adherent to the ileum was found. A mass the size of a large English walnut was felt in the omentum, attached to the cecum about 8 cm. above the appendix. An appendectomy was done and the mass was freed from the cecum and removed. The area was repaired and the wound was closed without drainage. The pathological report was as follows:

The appendix measures 6 cm. in length. The tip is bulbous and 1 cm. in diameter. Microscopical examination shows acute, subacute and chronic inflammation. A piece of omentum contains a firm, but elastic, mass of tissue, measuring 2 cm. in diameter, whose cut surface is yellowish gray and granular, showing some necrosis in the center. The omentum shows marked fibroblastic proliferation, young capillaries and marked infiltration with lymphocytes, plasma cells and eosinophils. Many giant cells are present. There is no evidence of caseation or necrosis. Diagnosis: regional ileitis.

Shortly after discharge from the hospital the patient developed multiple fistulas in the wound. Six months later a resection of the distal end of the ileum, cecum and ascending colon was done at a Boston hospital. Since then he has felt perfectly well.

*Comment* This case was diagnosed as recurrent appendicitis, which in the light of the history and physical findings seemed justified. A white-cell count of 18,000 and a red-cell count of 4,450,000 were compatible with a diagnosis of acute appendicitis. The formation of multiple fistulas as illustrated in this case is apparently a common complication.

*Case 5* (S. H. 122,990) L. S., a 53-year-old Italian, was operated on for a retrocecal appendix on February 5, 1936. Operation revealed a hard, irregular mass involving the mesentery and mesoappendix. The latter was bound down to the mass. The red-cell count was 4,600,000, the hemoglobin 80 per cent and the white-cell count 9500. The

patient was discharged with a diagnosis of chronic appendicitis and terminal ileitis. The pathological report on the appendix was as follows:

In the stroma of the mucosa there are numerous eosinophils and an occasional plasma cell. In the submucosa there is some lymphocytic infiltration, and an occasional plasma cell and eosinophil are seen. In the muscularis there is an area showing giant-cell formation. Around these giant cells there are numerous polymorphonuclear cells, a few lymphocytes and a scattering of eosinophils. Fibroblastic reaction is active, and there are numerous newly formed capillaries. This fibroblastic reaction extends into and to some degree distorts the muscular coats. The blood vessels just under the serosa are dilated and filled with red blood cells. This area just under the serosa shows perivascular infiltration of lymphocytes. A collection of lymphocytes with occasional polymorphonuclear and plasma cells and eosinophils is found in the meso-appendix. Diagnosis: subacute appendicitis, ? regional enteritis.

This patient has not been located since he was discharged from the hospital.

#### SUMMARY AND CONCLUSIONS

A series of 5 cases of regional enteritis are reported. From a study of the literature and of these cases, it is clear that many of the classic symptoms of the disease may be absent in a given case. Furthermore, there is a tendency for those in the younger age group to develop small-bowel lesions, whereas those in the older age group have large-bowel disease. In view of the varying conditions found at operation, no standard operative technic can be recommended. In the majority of cases the ultimate diagnosis rests on the pathologist.

From the literature and my own experience it seems that the longer a family has been in the United States the less liable its members are to have this condition, and one gathers the impression that the Jewish race is most prone of all to suffer from it.

The ileostomy saved a life and in no way interfered with later treatment. Until the pathologist made his report, the tumor was thought to be malignant. Without this report and our present-day knowledge, it might have been regarded as a cancer

*Case 2* (S. H. 131,085) F. F., a 54-year-old woman, was admitted to the hospital September 30, 1937 Her chief complaint was constipation with intermittent pain in her abdomen. For the past several years she had had to take laxatives daily She had had intermittent black stools and occasional vomiting The abdominal distress had recently become more persistent. Her appetite was poor and she had lost weight.

The physical examination was negative except for the gastrointestinal tract. The abdomen was generally tender with a feeling of fullness and a possible mass on the right side. On the day of entrance the red-cell count was 4,800,000, the hemoglobin 95 per cent and the white-cell

count 17,000 The following day, with a diagnosis of intestinal obstruction, the abdomen was opened under drop ether anesthesia. A tumor was found that involved the cecum and ascending colon and almost completely obstructed its foramen A right colectomy was done by the Mikulicz method, staggering the ileum along the colon. A rubber tube was tied into the open end of the ileum, a Page clamp was left on the colon and the abdomen was closed in layers around the protruding ileum and colon An extensive involvement of the mesenteric lymph nodes was observed, but no nodules could be felt in the liver The pathological report was as follows

The section consists of the cecum, appendix, 6 cm. of terminal ileum and 10 cm. of ascending colon In the cecum is an ulcerated area, 4 cm. in diameter, with slightly raised, firm edges The crater of this ulceration is dark red and smooth. There is considerable narrowing of the ileocecal valve. Diagnosis regional ileitis

On October 13 the red-cell count was 4,170,000, with a hemoglobin of 80 per cent. On October 27 the patient was discharged to her home, but returned on November 3 for the closure of her colostomy stoma. On November 4 the red-cell count was 3,980,000, the white-cell count 12,400 and the hemoglobin 80 per cent. On November 21 a blood examination showed 6400 leukocytes and a red cell count of 3,650,000 On December 10 the patient was transfused with 420 cc. of whole blood, and 7 days later was discharged from the hospital. Since that time she has been clinically well.

*Comment* This case illustrates how easily regional ileitis may be mistaken for malignancy with partial obstruction In this case the white-cell count was raised but the red-cell count was normal, a condition not accounted for by dehydration On completion of the operation, it was believed that an obstructing malignancy had been removed.

*Case 3* (S. H. 123,951) A. T., a 40-year-old Frenchman, was first seen in April, 1936, with precordial pain His blood pressure was 180/120 He gave a history of epigastric pain about half an hour after meals He said that as a young man he had had a rash, and later had received three or four doses of arsphenamine. He denied ever having had a positive Wassermann He was admitted to the Springfield Hospital on June 10, giving a history of a gradual onset of general abdominal cramps and diarrhea with remissions of a week or less, similar symptoms having been noted 8 or 10 months previously He said he had lost 22 pounds in the last 3 months The blood pressure was 175/120, the heart and lungs were essentially normal, the abdomen was normal except for a mass resembling feces just to the right of the umbilicus The red-cell count was 4,050,000, the hemoglobin 70 per cent and the white-cell count 37,000 The urine was negative. The findings gave the impression of cancer of the lower bowel

Having developed a slight cold, the patient was sent home to recover from it. He returned on June 14 With a diagnosis of carcinoma he was operated on June 16 and a regional ileitis was found involving the terminal 25 cm. of the ileum, the cecum and all the ascending colon A Mikulicz resection of the ileum, cecum, ascending colon and hepatic flexure was done. The pathological report was regional ileitis The ileum and transverse colon were approximated and a Mixer glass tube was sutured into the open end of the ileum A clamp was left on the colon The wound was then closed in layers

On July 2 the redundant colonic spur was amputated by diathermy On July 23 the colostomy opening was

may be constant or inconstant in its presence, and despite its variability in size is always characterized by a feeling of elongation rather than of roundness. Tenderness varies in degree but is always present. Distention is the third most constant sign, but is usually late in appearance and is directly dependent on the degree of obstruction. Peristalsis can usually be seen, and the abdomen tends to remain soft in distinction to its rigidity in obstructions due to other types of lesions. The blood picture is not particularly characteristic. A low-grade anemia occurs in the chronic cases. The white blood cells increase rapidly as the intussusception develops, the count rising to about 20,000. Microscopic blood in the feces cannot be demonstrated until late in the disease. Shock is usually a late sign, and in this series was noted in only 1 case. X-ray findings are of very questionable value in the diagnosis of polyposis, especially after the clinical picture has developed to the point of obstruction from an intussusception. Prior to this, however, most writers agree that these tumors can be demonstrated roentgenologically by careful technic and interpretation.

Symptomatically, polyposis in the small intestine is marked by a fairly consistent pattern. The pain is generalized in the upper abdomen without localization. It is cramp-like and of variable duration and intensity. Nausea and vomiting usually follow the onset of pain, increasing with the rapidity and completeness of the obstruction. In the cases with a history of long-standing vague abdominal symptoms, nausea and vomiting were not prominent until the intussusception had developed and had remained long enough to cause obstruction. It is also to be noted that obstipation was a constant characteristic in our group and that no cases showed diarrhea. The chronicity of the symptoms was impressive, in 1 case they had been present for two weeks, and in another ten years.

The treatment of benign polyps is early surgical removal. In considering the method by which this may be best accomplished we find the technical procedure influenced by the type of lesion and by the complications already developed before operation. The solitary polyp, which according to Raiford<sup>2</sup> is the apex of the intussusception, is telescoped by traction into a lower portion of the bowel. He believes the mechanism of this type of intussusception is different from that in children where hypermotility, as well as irregular motility, of the bowel is the causative factor.

The simplest type of operation is excision of the polyp, after opening the bowel either in the long or transverse axis, and immediate closure. A primary resection of the involved portion is indicated when there are multiple polyps or when the via-

bility of the bowel is questionable. In this event a proximal enterostomy may complete the operation. In some cases, a two stage operative procedure comprising a lateral anastomosis, to be followed by a second-stage removal of the growth-bearing loop, may be the method of choice. We believe that the latter is preferable to a primary resection and anastomosis. Lastly, rather than do a primary resection in those cases where the viability is questionable or when we desire to obviate the danger of absorption, we prefer to remove the mass from the abdomen and suture a tube into the proximal bowel.

In this series of 7 operations, resection was performed twice: an end-to-end anastomosis and a side-to-side anastomosis. The remaining 5 consisted of simple excision of the polyp and immediate closure of the bowel. All the patients were discharged from the hospital well. The general opinion is that the prognosis is good when appropriate surgical measures are instituted early.

#### CASE REPORTS

*Case 1.* C. G., a 4-year-old boy, was admitted to the hospital March 22, 1918, complaining of abdominal cramps after eating, accompanied by occasional vomiting. These symptoms had persisted for 2 days prior to admission. He had been a full term, spontaneously delivered, normal infant. There was no history of childhood or familial disease. Physical examination disclosed an apprehensive child, well nourished and of normal development. The temperature was 98.5°F and the pulse 150. Physical examination disclosed negative findings except in the abdomen, which was soft, not distended, and free of rigidity and spasm. There was a large, doughy, non tender mass extending from the right to the left side of the midabdomen. The liver and spleen were not palpable. The white cells numbered 18,500, with 85 per cent polymorphonuclears. The urine was normal. Immediate operation was decided on. Through a right rectus exploration an intussuscepted mass involving the terminal 90 cm. of ileum was found. This mass was easily reduced. The bowel was of good color, and a small polyp was palpable at the head of the intussusception. The intestine was opened in its long axis, and a polypoid growth the size of a walnut was removed. The incision in the bowel was closed and the abdomen was closed without drainage. Recovery was uneventful, and the patient was discharged well in 15 days.

The patient was readmitted 8 months after discharge complaining of abdominal distress of recent onset. Abdominal examination revealed a well healed wound with no evidence of any mass. The temperature and pulse were normal. Repeated enemas showed small, hard fecal masses, but no blood or mucus. The red-cell and white-cell counts were both normal. No x-ray investigation was attempted because the patient's symptoms subsided and he was discharged.

Ten years after the second admission he began to have vague abdominal pain, referred chiefly to the region of the umbilicus, accompanied by occasional vomiting and obstipation. These symptoms persisted off and on for 6 weeks. X-ray examination revealed no abnormalities, and there was no evidence of intestinal obstruction from adhe-

## POLYPOSIS OF THE SMALL INTESTINE\*

## A Report of Five Cases

ELIOT A. SHAW, M.D.†

PROVIDENCE, RHODE ISLAND

SINCE 1930 there has accumulated considerable information about tumors of the small intestine. Polyps may be defined as any type of benign tumor having a pedicle either short or long, they may be solitary or multiple. This discussion, however, will be limited to polyps of the adenomatous type, in contradistinction to the polypoid tumor whose histologic structure classifies it as fibroma, fibromyoma, leiomyoma, hemangioma, lipoma, lymphoblastoma, cyst or inflammatory tumor.

Raiford,<sup>1</sup> in a thorough study of tumors of the small intestine, found 88 in 11,000 autopsies and 45,000 surgical specimens of cases treated in the Johns Hopkins Hospital, 50 were benign and 38 malignant. Saint,<sup>2</sup> Cave<sup>3</sup> and Joyce<sup>4</sup> have each reported a small series of tumors of the small intestine, including a few benign growths. Cooke,<sup>5</sup> in reporting 11 cases of carcinoid tumors of the small intestine, of which 3 had malignant lesions, defined two anatomic types—adenocarcinoma and carcinoid. The former he believes is commoner, but both are rare. It is evident from the description of the lesions in his series that certain of the benign tumors were polyps although termed carcinoid.

Adenoma is the commonest of all the benign tumors found in the small intestine. An analysis of the cases collected by Raiford<sup>1</sup> shows 15 adenomatous polyps, of which 4 underwent malignant degeneration. Such polyps constitute between 16 and 23 per cent of all benign tumors of the small bowel. The entire literature yields only 339 reliably reported cases, a figure arrived at by Raiford,<sup>1</sup> Rowe and Neely.<sup>6</sup>

In a study at the Rhode Island Hospital extending from January, 1929, to July, 1938, among 18,944 surgical specimens and 2795 postmortem examinations only 3 small-bowel lesions of this nature were found. Among the surgical specimens 1 polypoid tumor of the jejunum with malignant degeneration was reported, and the autopsies disclosed 1 case with a single polyp of the duodenum and 1 with polyposis of the entire gastrointestinal tract. We must conclude, therefore, that this is not a common pathologic entity.

Most writers agree that these tumors of the small intestine occur with greatest frequency in its lower segment. Their distribution is noted in Table 1. In our series 1 tumor had undergone malignant degeneration, a percentage comparable to the figures given by other investigators.

Age is a variable factor, and while these tumors appear to occur and recur in younger individuals, no age group is immune. The adenomatous types may be congenital. The necessity for reoperation in 2 cases of this series after the removal of a single

\*One case showed polyps in both the jejunum and ileum.

benign polyp indicates either the re-formation of this type of tumor or failure to remove all polyps at the time of the original operation. Occurrence does not appear to favor either sex, nor does race seem to be a factor.

The pathology is quite constant. Grossly the polyps vary in size from that of a marble to that of a plum and are very friable, differing little from other types. The mucous membrane is dark red and convoluted, and follows the general outline of the growth. The polyps present a mushroom-like appearance, and this fungating structure is also seen on section. The friable masses of glandular tissue projecting outward in finger-like processes at the periphery are lined with columnar epithelium and surround a central stalk-like portion of fibrous connective tissue coming directly from the intestinal wall.

The outstanding clinical feature of polyposis of the small intestine is the production of an intussuscepted mass. In Raiford's<sup>1</sup> series, this occurred in 23 per cent of the cases with benign tumors. In Joyce's<sup>4</sup> cases the percentage of intussusception was 30, and it happened much more frequently in benign than in malignant growths. In our own group intussusception occurred in every case. The mass is usually in the left side of the abdomen, and is solid but doughy and freely movable. It

of the bowel was re-established by an end-to-end anastomosis, and the abdomen was closed without drainage. The patient made an uncomplicated recovery and was discharged well in 21 days.

The pathological diagnosis was adenocarcinoma of the jejunum. Grossly the tumor presented a ragged, reddish yellow gray, mucoid, cauliflower like mass, measuring 8 cm. in its greatest diameter. Its base measured 3 cm. in the longitudinal plane of the bowel segment. Transversely it extended around the entire surface of the bowel wall. On section the polyp had a yellow gray granular appearance, with numerous small cavities containing yellow, cloudy, mucoid material. The mucosa of the bowel had a pinkish, glistening appearance and was not involved by the tumor mass. Microscopically the sections of the polypoid mass consisted of a branched fibrous connective tissue core, covered by columnar epithelium in which were seen many tall goblet cells. These were cylindrical and hyperchromatic. The epithelial tumor cells were arranged in a glandular manner and in cords, and varied in size and shape. Hyperchromatism was marked, and a few mitotic figures were seen. There were numerous mononuclear cells and lymphocytes, with a few plasma and polymorphonuclear cells in the fibrous connective tissue. In a few places the tumor extended into the muscle layer. The major part of the tumor mass showed a uniformity of cells and no mitotic figures.

**Case 4** M. M., a 15-year-old girl, was admitted to the hospital February 27, 1928, complaining of severe abdominal pain in the upper half of the abdomen, with nausea and vomiting, coming on immediately after breakfast. There had been no previous attacks. An enema gave good results, but despite this the pain increased in intensity. The past history was essentially negative. Abdomen

Figure 3 Case 5

*Barium meal film, showing several rounded areas of transparency that indicate the location of sclerol of the polyps*

inal examination revealed a generalized tenderness with moderate distention. The entire left rectus was rigid, with tenderness shifting from the epigastrium to the left lower quadrant. The rectal examination was negative. The white cells numbered 25,200, with 85 per cent polymorphonuclears. The abdomen was explored 6 hours after the onset. An intussusception was found in the mid jejunum and required a resection of the mass, followed by a lateral anastomosis. The patient made a good convalescence and was discharged well on the 15th postoperative day. Pathologically the specimen showed a peduncu-

lated papillary adenoma of the polypoid type, with slight invasion of the intestinal mucosa. There was no destructive invasion of the muscular coat of the intestine, and no indication of frank malignant growth. The diagnosis was papillomatous adenoma.

**Case 5** C. K., an 18-year-old boy, was admitted to the hospital March 17, 1938, with a diagnosis of intestinal obstruction. He complained of cramp-like pain in the upper abdomen radiating from right to left. Nausea and vomiting had been severe for 24 hours. The vomitus was bile stained. There had been two normal bowel movements since the onset of symptoms. The pain was ag-

Figure 4 Case 5

*Another film showing polyps at various locations*

gravated by reclining. The past history revealed three similar attacks, the first occurring 12 months and the last 2 weeks before admission. The other attack, which had occurred 8 months previously, was marked by the same symptoms and the patient was then hospitalized. A barium enema was administered at that time, following which a mass in the left lower quadrant disappeared and the patient was discharged. No blood had ever been noted in the stools.

Physical examination at the present admission disclosed a tall, pale, young adult, well developed and nourished and in obvious distress. A palpable and visible, firm, slightly tender, sausage shaped mass in the left lower quadrant was the only abnormal finding. There was no spasm, but peristalsis was visible. A barium enema caused disappearance of the mass. Blood counts showed a consistently lowered red-cell count and a white-cell count of 18,500, with a preponderance of polymorphonuclears. The feces showed repeated positive tests with benzidine. X-ray studies on 3 different days were not informative. The diagnoses of recurrent intussusception, pelvic kidney, and internal hernia were considered, and an exploratory laparotomy was performed 1 week after admission. The left rectus was incised for a distance of 18 cm., with the midpoint at the level of the umbilicus. On opening the peritoneal cavity the following lesions were noted. Beginning at the angle of Treitz the jejunum was markedly thickened and swollen. Multiple polyps varying in size from that of a peanut to that of a lime were freely movable on their pedunculated bases within the lumen of the bowel. In the terminal 30 cm. of the ileum numerous similar polyps were also encountered extending to the ileocecal valve. Intussusception had taken place in portions of the bowel un-

sions In the 8th week of these attacks the patient was seen in consultation by the surgeon who had previously performed the operation At that time the abdominal pain was constant and intense. There was some distention on the left side of the abdomen, through which could be palpated a sausage shaped mass, tender and doughy The temperature was 98.6°F and the pulse 96 A diagnosis of recurrent intussusception was made and immediate exploration was advised. The abdomen was opened medial to the scar of the previous operation, and an intussusception of the ileum was found. The apex again was formed by a polypoid tumor in the intestine, the size of an English walnut. The same surgical procedure was

The patient did well and was discharged at the end of 21 days

On January 28, 1916, 4 months after the previous admission, the patient was readmitted with a diagnosis of intestinal obstruction. She had been well until 2 weeks previously, when a recurrence of abdominal pain, with vomiting, began and increased daily Operation disclosed identical lesions The intussusception was reduced, and three adenomatous polyps were removed. The pathological diagnosis was adenoma. The sections showed glandular tissue arranged around a central lumen and forming papillary projections from a connective tissue base. The patient was discharged well on the 20th post operative day

Figure 1 Case 5

*Barium-enema film, showing a pattern relief in the cecum strongly suggesting intussusception Cecum is dilated, and no barium has entered the ileum*

followed as in the previous exploration—reduction of the intussusception and removal of the growth The patient was discharged well on the 14th postoperative day Five years after operation the patient was free of abdominal symptoms.

**Case 2** J McR., a 12-year-old girl, was admitted to the hospital September 6, 1915 The onset of illness began with sudden pain throughout the abdomen, associated with vomiting These symptoms persisted without interruption, and the bowels had not moved. The past history was non-contributory Physical examination revealed a soft, elongated mass in the right lower quadrant, slightly tender and freely movable. The white-blood-cell count was 15,000 The urine was normal, and an enema disclosed no blood or mucus in the stool A diagnosis of intussusception was made, and under ether anesthesia the abdomen was opened through a midline incision. A thick, swollen congested loop of jejunum was delivered into the wound and the intussusception was easily reduced. A polypoid mass was felt in the bowel at the apex of the intussusception. The bowel was incised and the mass, which proved to be a pedunculated polyp, was ligated at the base and removed. The bowel was sutured in its transverse diameter and the wound was tightly closed.

The pathological report described a soft, spongy mass the size of a walnut. On section it presented a dull gray surface, with several brownish streaks resembling the branching of a tree. Microscopically, the sections showed a large amount of fibrous tissue enclosing a hypertrophied glandular mass The epithelial lining of some of the glands had undergone hyaline degeneration, with an increase in the cell pigment. The glands were tortuous, but there were no atypical cells The diagnosis was adenoma

**Case 3** E. I., a 48-year-old, married woman, was admitted to the hospital February 11, 1938 Her illness had begun 10 years before, when she began to have intermittent epigastric pain almost daily This usually came on about half an hour after meals and was relieved by reclining Two weeks before admission the pain increased in frequency, duration and intensity, and was accompanied by almost continuous nausea and frequent vomiting Physical examination disclosed a well-developed, slightly malnourished, pale woman The blood pressure was 95/65 The skin was moist. Abdominal examination revealed a slightly tender, non fluctuant mass about the size of a lemon, which moved freely to all quadrants except to the right upper The mass appeared to be separate from the pelvic organs There was no associated spasm. There was slight distention. A flat plate of the abdomen gave

Figure 2 Case 5

*Repeat barium-enema film in six days after previous enema, no longer showing any evidence of intussusception and thus indicating spontaneous reduction coincident with a moderate abatement of symptoms The cecum shows an even, dense filling with barium*

no information. The red-cell count was 4,670,000 and the white-cell count 12,350, with 80 per cent polymorphonuclears. Occult blood was found in the stools on repeated examinations The abdominal cavity was explored through a right rectus muscle splitting incision and the mass, felt abdominally, proved to be a tumor of the jejunum 30 cm. distal to the ligament of Treitz. This area was resected well beyond the visible tumor in both directions. Just within the lumen of the proximal end of the resected jejunum was seen a pedunculated mass The tumor was easily removed after ligating its pedicle. The continuity

of the bowel was re-established by an end-to-end anastomosis, and the abdomen was closed without drainage. The patient made an uncomplicated recovery and was discharged well in 21 days.

The pathological diagnosis was adenocarcinoma of the jejunum. Grossly the tumor presented a ragged, reddish-yellow gray, mucoid, cauliflower like mass, measuring 8 cm. in its greatest diameter. Its base measured 3 cm. in the longitudinal plane of the bowel segment. Transversely it extended around the entire surface of the bowel wall. On section the polyp had a yellow-gray granular appearance, with numerous small cavities containing yellow, cloudy, mucoid material. The mucosa of the bowel had a pinkish, glistening appearance and was not involved by the tumor mass. Microscopically the sections of the polypoid mass consisted of a branched fibrous connective tissue core, covered by columnar epithelium in which were seen many tall goblet cells. These were cylindrical and hyperchromatic. The epithelial tumor cells were arranged in a glandular manner and in cords, and varied in size and shape. Hyperchromatism was marked, and a few mitotic figures were seen. There were numerous mononuclear cells and lymphocytes, with a few plasma and polymorphonuclear cells in the fibrous connective tissue. In a few places the tumor extended into the muscle layer. The major part of the tumor mass showed a uniformity of cells and no mitotic figures.

*Case 4* M. M., a 15-year-old girl, was admitted to the hospital February 27, 1928, complaining of severe abdominal pain in the upper half of the abdomen, with nausea and vomiting, coming on immediately after breakfast. There had been no previous attacks. An enema gave good results, but despite this the pain increased in intensity. The past history was essentially negative. Abdomi-

lated papillary adenoma of the polypoid type, with slight invasion of the intestinal mucosa. There was no destructive invasion of the muscular coat of the intestine, and no indication of frank malignant growth. The diagnosis was papillomatous adenoma.

*Case 5* C. K., an 18-year-old boy, was admitted to the hospital March 17, 1938, with a diagnosis of intestinal obstruction. He complained of cramp-like pain in the upper abdomen radiating from right to left. Nausea and vomiting had been severe for 24 hours. The vomitus was bile stained. There had been two normal bowel movements since the onset of symptoms. The pain was ag-

nal examination revealed a generalized tenderness with moderate distention. The entire left rectus was rigid, with tenderness shifting from the epigastrium to the left lower quadrant. The rectal examination was negative. The white cells numbered 25,200, with 85 per cent polymorphonuclears. The abdomen was explored 6 hours after the onset. An intussusception was found in the mid jejunum and required a resection of the mass, followed by a lateral anastomosis. The patient made a good convalescence and was discharged well on the 15th postoperative day. Pathologically the specimen showed a peduncu-

lated by reclining. The past history revealed three similar attacks, the first occurring 12 months and the last 2 weeks before admission. The other attack, which had occurred 8 months previously, was marked by the same symptoms and the patient was then hospitalized. A barium enema was administered at that time, following which a mass in the left lower quadrant disappeared and the patient was discharged. No blood had ever been noted in the stools.

Physical examination at the present admission disclosed a tall, pale, young adult, well developed and nourished and in obvious distress. A palpable and visible, firm, slightly tender, sausage shaped mass in the left lower quadrant was the only abnormal finding. There was no spasm, but peristalsis was visible. A barium enema caused disappearance of the mass. Blood counts showed a consistently lowered red-cell count and a white-cell count of 18,500, with a preponderance of polymorphonuclears. The feces showed repeated positive tests with benzidine. X-ray studies on 3 different days were not informative. The diagnoses of recurrent intussusception, pelvic kidney, and internal hernia were considered, and an exploratory laparotomy was performed 1 week after admission. The left rectus was incised for a distance of 18 cm, with the midpoint at the level of the umbilicus. On opening the peritoneal cavity the following lesions were noted. Beginning at the angle of Treitz the jejunum was markedly thickened and swollen. Multiple polyps varying in size from that of a peanut to that of a lime were freely movable on their pedunculated bases within the lumen of the bowel. In the terminal 30 cm. of the ileum numerous similar polyps were also encountered extending to the ileocecal valve. Intussusception had taken place in portions of the bowel un-

der direct vision, this was caused by the polyps and was easily reduced. There were numerous enlarged lymph nodes in the mesentery, and there were several calcified nodes on the medial side of the head of the cecum. The extent of the polyps precluded resection or short-circuiting. A large polyp was removed from the jejunum, the intestine was closed and the abdominal wound was sutured in layers. The patient was discharged at the end of 37 days.

Figure 5 Case 5

*Ureteropyelogram showing infantile left kidney also an anomaly—spina bifida—of the first segment of the sacrum*

unimproved, with a diagnosis of multiple polyposis of the small intestine. The pathological diagnosis was an adenomatous polyp.

On April 7 barium meal studies of the gastrointestinal tract were made at 30-minute intervals. As the barium progressed through the small intestine there were noted a large number of rounded defects within the lumen of the jejunum and ileum, but there was no marked delay at any point. The x-ray findings indicated the presence of numerous small tumors of the small intestine, scattered from the jejunum to the terminal ileum without producing obstruction.

#### CONCLUSIONS

We believe that polyps of the small intestine are a relatively rare clinical entity and are of particularly important clinical significance, for the following reasons. They have a tendency to malignant degeneration and can produce an intestinal obstruction by intussusception. They can occur in any age group, and may be congenital. They apparently never attain sufficient size to cause obstruction by occlusion.

Preoperative diagnosis is difficult and not frequently made, because the early signs and symptoms may seem to the patient so insignificant that medical advice is not sought, and an acute abdominal crisis is usually the basis for the surgeon's

first contact. More careful roentgenologic study of the small bowel, especially in routine gastrointestinal examinations when the signs and symptoms are obscure, may lead to early diagnosis and treatment. This will avoid the complications inherent in these polyps, namely malignant degeneration and the production of obstruction by intussusception.

#### DISCUSSION

DR. HORACE K. SOWLES, Boston: We had an interesting case at the Massachusetts General Hospital, which brings

Figure 6 Case 5

*Low power photograph of removed polyp showing characteristic finger like projections lined with columnar epithelium*

up a question mentioned by Dr. Shaw, namely whether or not polyposis is a congenital disease. The patient was a married woman of forty. One child, a girl, had died of intussusception, which was caused by a polyp; she was operated on at the Children's Hospital but had not been sent there until the intestine had become gangrenous. A brother was known to have extensive polyposis, and her father had died of a disease which was probable polyposis or malignancy of the large bowel.

The patient had had symptoms for a long time. She had been a patient at the Boston City Hospital, with in definite gastrointestinal symptoms, a probable diagnosis of gall-bladder disease had been made there, but operation had not been advised. Like many patients with chronic disease who wander from one clinic to another, she appeared at our clinic with the same gastrointestinal symptoms, and one of the doctors in the X-ray Department, who has shown uncanny ability in picking up unusual gastrointestinal lesions, discovered multiple polyps in the small and large bowel. They were largely localized in the duodenum, but several were in the lower jejunum and upper ileum as well as in the large bowel.

Dr Edward L. Young operated but resected no bowel. He made multiple incisions in the small intestine and excised eight polyps. The patient made a good recovery and went home, but came back four months later—in July, 1938. This time the case was taken over by Dr Arthur W. Allen, who decided on a very radical operation because of the extensive polyposis which had been demonstrated in the large bowel. At this time no more polyps were found in the small bowel. Dr Allen did an almost complete colectomy, removing the colon from the cecum down to the rectosigmoid junction, and doing an anastomosis of the terminal ileum to the rectum. One pedunculated polyp which remained in the lower segment of the rectum was removed from below through a proctoscope.

We think at the present time that all the lesions of the large bowel have been removed, with the possible exception of one in the lower rectum, which we intend to follow from time to time with the aid of a proctoscope. We cannot be absolutely sure whether or not there are any more polyps, either present or developing, in the small intestine. Since this seems an unusual and interesting case, the patient will be kept under observation.

DR. THOMAS H. LANNAN, Boston. Dr Sowles brings up the question of a familial history and mentions a child who came to the Children's Hospital. We have

been encountering more of these polyps, not only in the large bowel but also in a surprising number in the small bowel. In 3 cases there has been a familial history.

In the case described by Dr Sowles the child did come to the hospital with a gangrenous intussusception, and died there. Members of the house staff pointed out somewhat caustically that within twenty-four hours she had been at another hospital, and had been discharged with a statement that nothing was wrong. Their triumph was very short-lived, because in going over the old history it was found that the child had been a patient at the Children's Hospital and had been thoroughly examined, though nothing was found. On account of the vagueness of the symptoms, we even sent her to the Psychiatric Service as a 'problem child.'

We have been quite impressed with the vagueness of symptoms in these cases, and the question arises as to whether we have been overlooking a good many of them in the past. We have lately become convinced that a child who has these vague but persistent abdominal symptoms should receive most careful study, and should probably be explored.

DR. PETER P. CHASE, Providence. I should like to raise the question of the possible danger of excision of these polyps without an immediate pathological diagnosis. I realize that malignancy of the small intestine is very rare, but I had a case of this sort which was associated with intussusception. The growth was an adenocarcinoma, and it brings up the question of mistaking malignant polyps for benign ones.

DR. ALFRED M. ROWLEY, Hartford, Connecticut. The familial history of these cases makes one wonder what the exciting cause is. Embryonal influence does not explain it. Polyposis is common in Egypt and the Orient. I wonder whether amebiasis is the causative factor.

DR. SHAW (closing). I have nothing to add except to say that Dr Chase's point is well taken. I believe that a frozen section should be done in all these cases because of their tendency to undergo malignant degeneration.

## REPORT ON MEDICAL PROGRESS

## GYNECOLOGY

JOE V MEIGS, MD \*

BOSTON

THE purpose of this paper is to bring to the attention of the general practitioner and surgeon the advances of practical importance in this specialty during the last few years. There are many important but not as yet practical observations that are not included. Furthermore, the names of discoverers and investigators and the references will not be included, and it is hoped that they and the readers will understand the reason for this omission. So far as possible the advances will be taken up under special headings. There are so many new facts in the field of endocrinology that only the important ones which affect gynecology and have a useful bearing on treatment will be mentioned. The hormonal conditions will not be grouped together, but will be spread throughout the paper under the different headings where they best apply.

## METHODS AND AIDS IN DIAGNOSIS

Endometrial biopsy has come to be of great importance in abnormalities of the menstrual rhythm and in work on sterility. Tissue can now be removed from the endometrial cavity in the office without anesthesia, or at least with a very short anesthesia, and the patient can be allowed to go home. There have been very few accidents subsequent to this procedure, the most upsetting of them being interruptions of pregnancy. Rarely is a septic process started. The biopsy may be taken with a small punch, a suction curette or a small, cup-shaped curette that can pass the internal os. A very small piece of tissue preserved in Zenker's solution or formalin, and stained, is sufficient to give the pathologist an opportunity to determine the stage of the endometrium. If taken a few days before the oncoming menstrual period it should show a secretory or functional phase. If this is not present and the menstrual period occurs shortly after the biopsy, it is evidence that a satisfactory ovulation with corpus-luteum formation has not occurred. This simple test may explain a menstrual abnormality, such as menorrhagia, or a problem of sterility. Multiple weekly biopsies in patients with abnormal flowing may give a clue to a delayed ovulation and thus explain the abnormal rhythm. Other irregularities of the men-

strual cycle can thus be determined and investigated after experience in the use of this simple method.

The necessity for careful charting of the menstrual cycle by the patient is obvious, for without accurate knowledge of the time of the period no correct observations can be made. This can be easily done with ordinary graph paper—each square representing a day of the cycle. With thirty-one squares allowed for each month, and each month given a line on the graph, a satisfactory chart can be made. It is surprising after charting a series of patients' periods to note how unusual it is for any given patient to have regular periods. Patients should be taught to keep accurate records, and these should be noted on the physician's chart so long as there is any problem.

The hysterometer is an important adjunct, and should be used to determine the proportionate size of the body of the uterus and cervix. It is not the size of the uterus that makes for normality, but the proportion of the body to the cervix. The hysterometer consists of a uterine sound measured in centimeters with a coiled spring, and a cuff that can be moved up and down on the shaft of the sound. It is advanced to the internal os and the length of the cervix is measured, it is then advanced to the top of the fundus and the length of the uterus and cervix is measured. Knowing these, it is a simple matter by subtraction to ascertain the length of the body of the uterus. The normal proportion between the lengths of the body and of the cervix is 2:1, the measurements of the juvenile or moderately underdeveloped uterus are the same for both, and in the infantile uterus the reverse of the normal holds true. These figures are only approximate, but in a patient with abnormal catamenia the added information as to whether the uterus is of normal or abnormal size is important. With the endometrial biopsy curette and the hysterometer, abnormalities of the ovaries and uterus are discovered. The ovary is the stimulator of an end organ, the uterus, and its activity is reflected in the endometrium and in the size of the uterus. Occasionally it can be assumed that an underdeveloped uterus with a normal endometrial cycle is due to a primary deficiency of the uterus itself.

The worth of the peritonoscope is beginning to

be appreciated. In abnormal menstruation and sterility it is practical, for with experience, changes in the ovary can be visualized, and the question of whether or not ovulation has occurred can thus be determined without operation. It is conceivable that a corpus luteum may form without ovulation, and the peritoneoscope affords a means of determining more accurately whether or not it has taken place by inspecting the ovaries for the corpus and the pelvis for blood and coagulum. Peritoneoscopy is done through a small incision in the abdomen. A trocar is passed, the peritoneal cavity is inflated with air and the instrument is passed into the abdominal cavity. The pelvic organs may be easily and satisfactorily inspected. The air is allowed to escape after the inspection is over, and the patient is ready to go home the next day. In the presence of abnormal menstrual function and in sterility problems such a procedure is of considerable value.

The peritoneoscope is still more useful in other gynecological studies than those concerned with ovulation. With this instrument an accurate diagnosis of pelvic disease can be made. In most cases of pelvic tumors and pelvic lesions it is not necessary to subject the patient to such an investigation, for the need for operation is usually obvious, but there are problems, such as whether a pelvic tumor is an ovarian tumor or a uterine fibroid, where accurate knowledge is of distinct value. It would be a serious mistake to adopt watchful waiting for ovarian cancer, a policy which would be wise in some cases of symptomless fibroids. The question of tuberculous salpingitis and peritonitis versus cancer with abdominal metastases can be settled, for biopsies can be taken through the peritoneoscope, and the bleeding spot can be cauterized. There are many possible uses for this instrument, and its value for making accurate diagnoses in pelvic conditions is certain to increase.

Hormone determinations, for example those of the follicle-stimulating hormone (F.S.H.) of the pituitary gland, of estrin or theelin and of the anterior-pituitary-like hormone of pregnancy urine (P.U.H.), continue to be of value. In the menopause, in patients with complete ovarian failure, in pituitary failure and in pregnancy, mole and chorionepithelioma, they are important diagnostic aids. In the menopause and in ovarian failure estrin is absent and F.S.H. is present, while in pituitary failure both F.S.H. and estrin are absent. In pregnancy P.U.H. is present, and in persistent bleeding following the passing of a mole or following a normal pregnancy or miscarriage the finding of a large amount of P.U.H. is a most important factor in making the diagnosis of malignancy of the chorion.

Molimina or premenstrual symptoms such as weeping, painful breasts, vaginal discharge, cramps, backache, change in disposition, and so forth constitute valuable evidence of ovarian activity. If a patient has molimina, estrin is present, and if she has cramps, ovulation has usually taken place. Thus in addition to the biological assay of urine, endometrial biopsy and so forth there is a simple method of detecting ovarian activity. Only recently has sufficient attention been paid to such symptoms.

Hirsutism may mean a great deal or very little. If present from childhood or if occurring in a hirsute family it is of but little consequence, but its sudden appearance may mean much. When it is accompanied by other symptoms such as amenorrhea or genital or breast atrophy, increase in the size of the clitoris, and so forth, a diligent search must be made for a tumor of the pituitary gland, adrenal gland or ovary. There are as yet no differential tests which enable one to separate these three lesions, but glucose tolerance tests, F.S.H. and estrin determinations, intravenous pyelograms, x-rays after the injection of air into the perirenal and periadrenal areas and peritoneoscopy are of value.

Congenital erosion of the cervix—the strawberry-red area the size of a ten-cent piece so often seen in nulliparas around the external os—is a valuable physical finding. It usually means that the uterus is not well developed, for this is a stigma of underdevelopment. The red area is made up of exposed endocervical glands. These are normally in the cervical canal, with the outside of the cervix covered with squamous epithelium. This lesion is often found in patients with sterility, dysmenorrhea or endometriosis. Its presence at once suggests that any pelvic abnormality may be due to underdevelopment or underfunction.

The colposcope is another instrument of considerable practical value. It consists of a bifocal microscope on a stand. It magnifies the outside of the cervix ten times, and gives the observer an excellent view of abnormalities of the cervical epithelium. Thus cysts of Naboth, exposed ducts of the endocervical glands and areas of leukoplakia, areas of pseudo-healing and abnormal epithelium can be easily detected. The colposcope when used in conjunction with Schiller's Lugol-solution test helps to identify early lesions of the cervix which may be dangerous. Most cervical tissue that does not stain with iodine is found to be an area bare of epithelium, one of chronic inflammation or one of hyperkeratosis or perhaps cancer. If biopsies are continuously taken from such areas, sooner or later small cervical cancers will be found. The

#### METHODS AND AIDS IN DIAGNOSIS

Endometrial biopsy has come to be of great importance in abnormalities of the menstrual rhythm and in work on sterility. Tissue can now be removed from the endometrial cavity in the office without anesthesia, or at least with a very short anesthesia, and the patient can be allowed to go home. There have been very few accidents subsequent to this procedure, the most upsetting of them being interruptions of pregnancy. Rarely is a septic process started. The biopsy may be taken with a small punch, a suction curette or a small, cup-shaped curette that can pass the internal os. A very small piece of tissue preserved in Zenker's solution or formalin, and stained, is sufficient to give the pathologist an opportunity to determine the stage of the endometrium. If taken a few days before the oncoming menstrual period it should show a secretory or functional phase. If this is not present and the menstrual period occurs shortly after the biopsy, it is evidence that a satisfactory ovulation with corpus-luteum formation has not occurred. This simple test may explain a menstrual abnormality, such as menorrhagia, or a problem of sterility. Multiple weekly biopsies in patients with abnormal flowing may give a clue to a delayed ovulation and thus explain the abnormal rhythm. Other irregularities of the men-

strual cycle can thus be determined and investigated after experience in the use of this simple method.

The necessity for careful charting of the menstrual cycle by the patient is obvious, for without accurate knowledge of the time of the period no correct observations can be made. This can be easily done with ordinary graph paper—each square representing a day of the cycle. With thirty-one squares allowed for each month, and each month given a line on the graph, a satisfactory chart can be made. It is surprising after charting a series of patients' periods to note how unusual it is for any given patient to have regular periods. Patients should be taught to keep accurate records, and these should be noted on the physician's chart so long as there is any problem.

The hysterometer is an important adjunct, and should be used to determine the proportionate size of the body of the uterus and cervix. It is not the size of the uterus that makes for normality, but the proportion of the body to the cervix. The hysterometer consists of a uterine sound measured in centimeters with a coiled spring, and a cuff that can be moved up and down on the shaft of the sound. It is advanced to the internal os and the length of the cervix is measured, it is then advanced to the top of the fundus and the length of the uterus and cervix is measured. Knowing these, it is a simple matter by subtraction to ascertain the length of the body of the uterus. The normal proportion between the lengths of the body and of the cervix is 2:1, the measurements of the juvenile or moderately underdeveloped uterus are the same for both, and in the infantile uterus the reverse of the normal holds true. These figures are only approximate, but in a patient with abnormal catamenia the added information as to whether the uterus is of normal or abnormal size is important. With the endometrial biopsy curette and the hysterometer, abnormalities of the ovaries and uterus are discovered. The ovary is the stimulator of an end organ, the uterus, and its activity is reflected in the endometrium and in the size of the uterus. Occasionally it can be assumed that an underdeveloped uterus with a normal endometrial cycle is due to a primary deficiency of the uterus itself.

The worth of the peritoneoscope is beginning to

\*Visiting surgeon, Massachusetts General Hospital, instructor in surgery, Harvard Medical School.

child undergoing treatment. It is well known that the adult vagina is rarely affected by the gonococcus, therefore if an adult state can be produced in a child, relief may be expected. This has proved to be the case, and all specific vaginitis in children should be so treated. Occasionally during treatment with estrin, breast development is started, but they revert to normal after cessation of treatment. The best method of treatment is to use children-size estrin suppositories every other day and to observe changes in the vaginal epithelium and in the number of gonococci present in the smear. The injection of at least 100 rat units of estrin in oil daily is safe, if this dose is not sufficient, it should be increased. Observance of the changes in the vaginal epithelium is most essential in the proper treatment of this condition.

Sulfanilamide is of value in the treatment of gonorrheal infections. Local infections of the urethra, Bartholin's glands, or cervix respond favorably, but infected tubes do not. Doses of 60 to 120 gr daily for at least seven days are essential, followed by smaller doses for at least another week or ten days. Smears must be taken frequently in order to check the presence or absence of the gonococcus, for sometimes the organism recurs even after satisfactory treatment. The morphology of the gonococcus changes during treatment, and its recognition in smears may be impossible. Cultures are of extreme importance, and it is essential that the culture media be freshly made on blood or ascitic meat-infusion agar and kept at body temperature. The agar plates must be returned to the laboratory for incubation immediately after inoculation. Successive negative cultures must have been obtained before a patient can be considered relieved of her gonorrhea.

Senile vaginitis is due to infections occurring in atrophied vaginal epithelium. Atrophic epithelium, like the epithelium of the very young, does not resist infection, and trauma may easily lead to superficial infection and ulceration. The method of treatment is to change the senile state of the epithelium to a normal adult one. This can be done by using suppositories of estrin (2000 and 3000 rat units) every other day, or even less frequently. The effect can be easily checked by vaginal smears, they should show the replacement of transitional or rounded epithelial cells by squamous or squared cells with nuclei. Pus disappears from the smear, and bacteria vanish. The vaginal estrin may be reinforced by estrin given orally or hypodermically in large or small doses, as necessary to change the cells to the normal adult type.

Pruritus vulvae and leukoplakial vulvitis are as a rule due to infections in non resistant atrophied

vulval tissues. This atrophy is caused by a lack of the ovarian hormone, and the use of the latter is recommended as treatment. Often these difficult and persistent lesions clear up if vaginal suppositories are used in addition to estrin given orally or hypodermically. It is best to use large doses at first, reducing them as relief is obtained. For intractable pruritus, alcohol injected into the periphery of the lesion is valuable. It is suggested that two minims of 95 per cent alcohol be injected in areas 0.6 to 1.0 cm apart at the periphery of the area of pruritus. Not over 10 or 20 cc of solution should be injected at any one time. This is not an office procedure but a hospital one, considerable swelling of the vulva may occur and it may remain painful for some time. Sloughs are not unknown. It has been suggested that section of the nerves that supply the skin of the vulva is valuable. This method is also of distinct merit in cases of kraurosis, as a resultant increase in blood supply relieves the atrophic condition. The pudendal and perineal nerves are resected, the absence of pain, burning and itching relieves the necessity for scratching, and this clears up the mild infection. In obstinate cases it may be necessary to do a vulvectomy. This is a minor procedure and can be done in a very short time, and the relief obtained is instantaneous. However, it must be remembered that along the edge of the incision the same process sometimes reappears, and in a few months or years the condition may be the same as ever. Surgery, alcohol injection, nerve section and hormone treatment are all possible in the treatment of severe itching and skin changes of the vulva.

Chronic endocervicitis is often not due to the gonococcus but the secondary invaders which infect the deep and branching cervical glands, plugging the ducts and causing the formation of cysts (cysts of Naboth). The process is often so extensive that nothing short of total hysterectomy suffices to cure it. In some cases linear cauterization of the cervix is the proper treatment, in others with deeper penetration Hyams's method of conization is the best procedure. Hyams uses a triangular wire on an electrode of the endothermy apparatus. With a cutting current a cone of cervix is removed. Healing is complete in about six weeks, a fresh cervical epithelium is present and most of the low endocervical glands have been destroyed. This is a simple method, but the possibility of hemorrhage on or about the tenth day must be thought of, as well as infection and, last and most important, cicatricial stenosis of the cervical canal. The latter means constant dilatation of the os or total removal of the cervix or entire uterus so as to keep the patient comfort-

white, raised plaque found at the junction of the squamous and endocervical epithelium, if it does not stain with Lugol's solution and is opaque and dull, is a dangerous area, and a real biopsy, not a mere scraping of the superficial epithelium, should be carried out at once. There is at present no instrument that will satisfactorily remove cervical biopsy material in the office, and it is not to be wondered at that early cervical cancers are not oftener found and cured. There is no doubt of the worth of these two methods of investigation, the Schiller test is simple and the colposcope, while at present of value only to the expert, will prove more valuable as additional physicians are trained in its use.

A proper solution for the Schiller test is as follows: iodine, 2 parts, potassium iodide, 4 parts, distilled water, 300 parts. It can be applied by means of a heavily soaked cotton pledget, a spray or a medicine dropper. The cervix must be cleared of mucus and must not bleed. The solution rarely causes any burning sensation. It should be left on the cervix for at least five minutes, and the excess should be removed without trauma.

#### INFLAMMATIONS

By far the commonest cause of vaginal discharge is *Trichomonas vaginalis*. This flagellate causes an irritating discharge with a characteristic pungent odor. Usually the discharge is yellow-green and contains air bubbles, it causes a disagreeable sensation in the vagina and is often accompanied by irritation of the vulva and the insides of the thighs. An accurate diagnosis is easily made by microscopic examination. The best method is to place a drop or two of the discharge on a slide, mix it with two or three drops of warm tap water, cover the mixture with a coverslip and examine it under the 4 mm lens of the microscope with the light cut down about one half. In such a slide squamous epithelium, pus cells and bacteria are seen, and often in the midst of such structures a few or many organisms of the size of a pus cell are found jerking and moving about, sometimes from side to side, sometimes in circles, close observation will disclose small, whip-like flagella which are responsible for the motion. Occasionally a phagocytizing leukocyte full of active bacteria is confusing, but on further observation it will be obvious that the motion is on the inside and not on the outside. Once the diagnosis is made, — and this is easy after a little experience, — treatment should commence. As any douche kills most of the organisms, and as most patients take a douche before visiting the office, it is frequently necessary to ask them to return at a time when they have made no attempt

to get rid of the discharge, this point should be remembered whenever a patient complains of a discharge. In spite of the fact that almost any kind of douche destroys the organisms, they reappear when the irrigations are stopped. Treatments of this type will not cure the disease. Since the flagellates are frequent inhabitants of the gastrointestinal tract, it is essential to advise the patient that the anus be wiped carefully with moist tissue or cotton from vagina to rectum, in order to avoid contaminating the former with feces. In persistent cases the bladder must be investigated, since trichomonas sometimes grow there, and if the patient is married, the husband must be examined, for he may be a carrier.

The most successful method of treatment is the use of Stovarsol in a powder-blower once a week, and douches of sodium perborate — one tablespoonful to one quart of warm water daily. Silver picrate powder in a blower and silver picrate suppositories are also satisfactory. If these methods fail, Stovarsol insufflations may be tried every day throughout the month, including the days of menstruation. Persistence is essential. Occasionally a few treatments suffice, but usually the treatment is long and recurrences are frequent. Patients should return two or three days after each menstrual period without having had any form of medication, and be examined for the organism. This is the time when it is most likely to be present. The condition is easy to relieve, but it is difficult to rid the patient permanently of this disagreeable vaginal parasite.

Monilia, a branching form of yeast, also causes a vaginal discharge and irritation, and the diagnosis is best made by culture. The discharge is irritating and watery and contains flecks of white fibrin. The discharge is usually typical, but a culture is the safest way to be sure of the diagnosis. Monilia is a frequent cause of discharge and vulvitis in diabetic patients. Treatment consists of the care of the diabetes, if present, cleanliness, warm alkaline douches and frequent painting of the vagina and vulva with a 1 or 2 per cent aqueous solution of gentian violet. Other yeasts occasionally cause persistent irritating discharge, and a more frequent use of cultures aids in making clear the etiology. The treatment is the same as for monilia.

Vulvovaginitis of gonorrheal origin in children is aided by the use of estrin, in vaginal suppositories, by injection or by mouth. The rationale of such treatment is the change of the non-resistant transitional epithelium of the prepubertal vagina to the gonococcus-resistant squamous epithelium of adults. Such a change can be observed microscopically by taking occasional smears from a

its own confines, surgery should be conservative, otherwise radical

For all the above tumors of the ovaries and tubes, x-ray treatment helps to relieve symptoms and prolong life but does not destroy the lesion

It has long been known that fibroma of the ovary is often accompanied by ascites, but until recently it was not known that pleural effusion might also be present in this condition. Cases with this syndrome are now being reported. It is important for all to realize that because a patient has a tumor in her pelvis with fluid in the abdomen and chest it is not necessarily malignant, it may be benign. In unexplained pleural effusion a careful search should be made in the pelvis for an ovarian tumor. The mechanism of the fluid in the chest is not known, but that it occurs is certain.

Endometriosis is very common, and great care must be used in inspecting the pelvis and marking specimens for the pathologist. Small, dark-blue to black spots on the uterus, ovaries, uterosacral ligaments, pelvic peritoneum or intestines, or a posterior cul-de-sac that is drawn up onto the back of the uterus, means endometriosis. Pregnancies are frequently reported following conservative surgery. If conservation of the ovaries is desired it is necessary to remove all visible areas of disease. Endometrial tumors of the rectosigmoid are not uncommon and are frequently confused with cancer. If endometriosis is suspected the pelvis and more especially the ovary should be searched for areas of the disease. If confirmatory lesions are not found and the diagnosis is in doubt, a colostomy that can eventually be closed and replaced in the abdomen is the proper operative procedure. If possible, resection and suture should be carried out if the actual diagnosis cannot be made. If an endometrioma is causing obstruction or partial obstruction, temporary colostomy with removal of the ovaries will allow atrophy of the tumor to take place, just as ovarian excision or the normal menopause causes atrophy of the endometrium.

Simple cysts of the ovary do not justify its removal. If it is possible to excise a cyst and reconstruct the ovary, or even to puncture a cyst, it is much wiser to do so than to remove the ovary. Removal of a gonad in a young girl often turns out to be a very unwise procedure. Following unilateral ovariectomy, abnormal bleeding, anovulatory cycles and menstrual upsets often occur. Such patients are frequently sterile, and a procession of operative procedures often follows.

These small cysts may be atretic or disappearing follicles, or may be persistent follicle cysts. Such

cysts are indicative of abnormal physiology, not tumors. Rupture or puncture or excision is sufficient treatment. Their presence is not an indication for ovariectomy, but quite the contrary.

The diagnosis of hydatidiform mole and chorion-epithelioma is made easier by the realization that a persistent Aschheim-Zondek test following abortion, mole or normal pregnancy means abnormality. If such a test is a strongly positive one and if a large amount of P U H is found, chorion-epithelioma should be suspected, if symptoms of bleeding persist, radical surgery should be done at once. The study of hormones has increased our ability to attack the problem of abnormal growth of the chorion.

#### STERILITY

The use of a hystrometer to determine the normal or underdeveloped uterus, and that of endometrial biopsy to determine whether ovulation occurs and about when, are advances in the study of sterility. The use of daily rectal temperatures helps to determine the date of ovulation. A drop in morning temperature about the middle of the menstrual cycle probably indicates follicle rupture. Uterine insufflation and the injection of lipiodol to determine tubal patency and to picture the inside of the uterine cavity and tubes are of value. A well-balanced diet with a normal amount of protein, carbohydrate and fat must be given. The rhythm is of extreme importance. It is not yet possible to say that only one ovulation occurs per cycle and that it occurs just two weeks before the oncoming period, but it probably does. It is possible to set the probable date of ovulation fairly satisfactorily. This is done by taking the shortest time and the longest time in days between the onset of periods and subtracting fourteen days from each. For safety's sake it is best to take three days off the smaller figure and add two days to the longer. This gives an interval during which ovulation probably takes place. Thus if the short interval were twenty-four days and the long interval thirty days, subtracting fourteen days from each would give ten and sixteen days respectively. Taking three from ten and adding two to sixteen would give seven and eighteen days as the most probable ones for ovulation and impregnation. Intercourse should be limited to these days, if pregnancy is desired. Occasionally between periods there is a menstrual like pain or gas pain known as *Mittelschmerz*. Sometimes there is a small flow, *kleine Regle*, at about the same time. These two phenomena probably denote the approximate time of ovulation and that when impregnation is most likely to occur.

able Pelvic cellulitis following any cauterization of the cervix may be extremely serious. Cauterization of a very shallow type is excellent treatment for exposed endocervical epithelium without deep infection. High amputation of the cervix can be done for endocervicitis, but the higher the amputation the greater the danger during pregnancy and the more chance of stenosis and poor function. If the endocervicitis is persistent and simple measures do not relieve it, total hysterectomy must be performed.

Pelvic inflammation of the gonorrheal or puerperal type should be treated as usual: rest in bed, pelvic heat, hot douches, sitz baths or the Elliott method of constant dry heat. Radical surgery should be avoided in acute cases with peritoneal irritation, pelvic and broad-ligament abscesses should be evacuated by simple drainage. When chronic inflammation is persistent, surgery should be carried out, and should be radical, for conservative pelvic surgery in these cases usually leads to dysmenorrhea, menorrhagia and other annoying pelvic disorders. If both tubes are excised, the uterus and cervix should be removed, if the patient's condition is satisfactory. If the genitalia can be preserved they should be in girls and young women, but in older patients radical surgery is best. The use of sulfanilamide in pelvic inflammation has not been completely successful, although certain reports are encouraging. In puerperal sepsis due to the hemolytic streptococcus it should certainly be used, and because of its action on the gonococcus its employment in gonorrheal inflammations seems logical.

#### TUMORS

The treatment of cervical cancer is best carried out by means of combined x-ray treatment plus moderate doses of radium. It is apparently better to combine the two than to use radium alone. X-ray treatment causes a diffuse fibrosis about the tumor and can be given in doses sufficient to kill tumor cells. This effect combined with local treatment of the cervix with radium is satisfactory. Surgery still continues to have advocates, but the operation must be done in early cases and must be one of the radical Wertheim-Clark type. Radium has now been in successful use for twenty-five years, but there are still those who advise surgery. Surely it is unwise unless carried out very radically and very expertly.

Cancer of the fallopian tube is commoner than supposed, and should be considered in the differential diagnosis in women with pelvic masses and bleeding near, at or after the menopause. The lesion occurs oftenest in relation to old pelvic in-

flammation and hydrosalpinx, but may occur as a simple tumor of the tube alone. Its characteristic symptom is that of bleeding from the uterus. Curettage is usually negative. This tumor bleeds into the endometrium and not from it. It should always be considered after the menopause when no curetings are obtained.

Cancer of the ovary has been demonstrated to be a highly malignant and not a common tumor. The results of treatment are exceptionally poor, yet from the nature of the tumor it should be easy to diagnose and remove. Any mass in the adnexal region should be considered as ovarian cancer until proved otherwise. If it is present radical surgery should be carried out. In both tubal and ovarian cancer, because of the possibility of the ovary, uterus and cervix being involved, total hysterectomy with bilateral salpingo-oophorectomy should be the operative procedure.

Tumors with endocrine significance are not uncommon and should be thought of in connection with ovarian masses, especially when there are changes in the patient's physical characteristics and symptoms of abnormal bleeding are present. The granulosa-cell tumor is the commonest endocrine one of the ovary. It is of a moderate degree of malignancy. This tumor may be responsible for both amenorrhea and abnormal uterine bleeding. It is frequently the cause of precocious puberty and bleeding after the menopause, and should always be thought of in connection with these two problems. Simple removal of the tumor is usually all that is necessary, but if there is any evidence of extension, radical surgery and x-ray treatment should be carried out. The dysgerminoma has no real endocrine significance but is often present in patients with poor genital development. A small vagina or an infantile uterus or both may be present in a patient with this tumor. The dysgerminoma in women is similar histologically to the seminoma of the testicle, but is not so malignant. If this tumor, a rounded, solid one made up of large round cells and often confused with rapidly growing cancer, is present in a young woman, conservative surgery should be practiced unless the tumor is bilateral or shows signs of invasion. If the tumor is within its capsule, conservative surgery should be done, otherwise radical. The arrhenoblastoma (from *arrhenos*, meaning "male") is a tumor of the ovary that secretes the male hormone and is responsible for progressive changes toward masculinity. It is usually unaccompanied by changes in the blood pressure or obesity, but does cause hirsutism, male voice, atrophy of breasts, large clitoris, striae, amenorrhea, and so forth. This tumor is somewhat malignant, but if it is within

its own confines, surgery should be conservative, otherwise radical

For all the above tumors of the ovaries and tubes, x-ray treatment helps to relieve symptoms and prolong life but does not destroy the lesion

It has long been known that fibroma of the ovary is often accompanied by ascites, but until recently it was not known that pleural effusion might also be present in this condition. Cases with this syndrome are now being reported. It is important for all to realize that because a patient has a tumor in her pelvis with fluid in the abdomen and chest it is not necessarily malignant, it may be benign. In unexplained pleural effusion a careful search should be made in the pelvis for an ovarian tumor. The mechanism of the fluid in the chest is not known, but that it occurs is certain.

Endometriosis is very common, and great care must be used in inspecting the pelvis and marking specimens for the pathologist. Small, dark-blue to black spots on the uterus, ovaries, uterosacral ligaments, pelvic peritoneum or intestines, or a posterior cul-de-sac that is drawn up onto the back of the uterus, means endometriosis. Pregnancies are frequently reported following conservative surgery. If conservation of the ovaries is desired it is necessary to remove all visible areas of disease. Endometrial tumors of the rectosigmoid are not uncommon and are frequently confused with cancer. If endometriosis is suspected the pelvis and more especially the ovary should be searched for areas of the disease. If confirmatory lesions are not found and the diagnosis is in doubt, a colostomy that can eventually be closed and replaced in the abdomen is the proper operative procedure. If possible, resection and suture should be carried out if the actual diagnosis cannot be made. If an endometrioma is causing obstruction or partial obstruction, temporary colostomy with removal of the ovaries will allow atrophy of the tumor to take place, just as ovarian excision or the normal menopause causes atrophy of the endometrium.

Simple cysts of the ovary do not justify its removal. If it is possible to excise a cyst and reconstruct the ovary, or even to puncture a cyst, it is much wiser to do so than to remove the ovary. Removal of a gonad in a young girl often turns out to be a very unwise procedure. Following unilateral ovariectomy, abnormal bleeding, anovulatory cycles and menstrual upsets often occur. Such patients are frequently sterile, and a procession of operative procedures often follows.

These small cysts may be atretic or disappearing follicles, or may be persistent follicle cysts. Such

cysts are indicative of abnormal physiology, not tumors. Rupture or puncture or excision is sufficient treatment. Their presence is not an indication for ovariectomy, but quite the contrary.

The diagnosis of hydatidiform mole and chorion-epithelioma is made easier by the realization that a persistent Aschheim-Zondek test following abortion, mole or normal pregnancy means abnormality. If such a test is a strongly positive one and if a large amount of P U H is found, chorion-epithelioma should be suspected, if symptoms of bleeding persist, radical surgery should be done at once. The study of hormones has increased our ability to attack the problem of abnormal growth of the chorion.

#### STERILITY

The use of a hystrometer to determine the normal or underdeveloped uterus, and that of endometrial biopsy to determine whether ovulation occurs and about when, are advances in the study of sterility. The use of daily rectal temperatures helps to determine the date of ovulation. A drop in morning temperature about the middle of the menstrual cycle probably indicates follicle rupture. Uterine insufflation and the injection of lipiodol to determine tubal patency and to picture the inside of the uterine cavity and tubes are of value. A well-balanced diet with a normal amount of protein, carbohydrate and fat must be given. The rhythm is of extreme importance. It is not yet possible to say that only one ovulation occurs per cycle and that it occurs just two weeks before the oncoming period, but it probably does. It is possible to set the probable date of ovulation fairly satisfactorily. This is done by taking the shortest time and the longest time in days between the onset of periods and subtracting fourteen days from each. For safety's sake it is best to take three days off the smaller figure and add two days to the longer. This gives an interval during which ovulation probably takes place. Thus if the short interval were twenty-four days and the long interval thirty days, subtracting fourteen days from each would give ten and sixteen days respectively. Taking three from ten and adding two to sixteen would give seven and eighteen days as the most probable ones for ovulation and impregnation. Intercourse should be limited to these days, if pregnancy is desired. Occasionally between periods there is a menstrual-like pain or gas pain known as *Mittelschmerz*. Sometimes there is a small flow, *kleine Regle*, at about the same time. These two phenomena probably denote the approximate time of ovulation and that when impregnation is most likely to occur.

## DYSMENORRHEA

The treatment of dysmenorrhea by means of hormones is disappointing, but before long a treatment may be evolved that will do away with surgery. Dilatation of the cervix is not satisfactory, but should be done before resection of the presacral nerve or superior hypogastric neurectomy. There is no doubt of the efficiency of the latter operation, for successful cases have been reported where it has been done without other operative procedures. The success of neurectomy is reported as 75 to 85 per cent, and such results are satisfactory for any operative procedure. The operation is not dangerous but is painstaking and difficult, and all the superior hypogastric plexus must be removed to assure success. Coitus is satisfactory following the operation, and pregnancy occurs in a high percentage of cases. In some patients labor pains are eliminated during delivery.

## THE MENOPAUSE

The treatment of the menopause by estrin is most satisfactory. The hormone can be given by intramuscular injection, by mouth or by vaginal suppository. It is decidedly more efficacious by injection, but oral administration is good. The proper way to treat patients is to give large doses (10,000 rat units) biweekly at first, and to cut the dosage down as low as possible when relief is obtained. Estrin is helpful in premenstrual tension, dysmenorrhea, night sweats, dizziness and even in involutional melancholia. There is no doubt as to its worth in various complaints of women at the menopause.

## MENSTRUAL DISTURBANCE

Disturbance of the menstrual rhythm, such as too frequent periods and delayed periods, are usually due to early or late ovulation. In some instances ovulation does not take place for a month, and in that case the period should come two weeks later, or in six weeks. This has been proved many times by weekly endometrial biopsies. In some women there is no ovulation rhythm and therefore their periods have no regularity, but arrive two weeks after each ovulation. This peculiarity does not mean lack of fertility, but it is difficult to advise such patients as to when ovulation takes place.

Pregnancy urine hormone is still of value in the treatment of abnormal bleeding. Progesterin and testosterone (testicular hormone) are advocated, and in some clinics good results are being obtained. The latter methods are expensive, as large doses are necessary and at the present time the cost is prohibitive. If the P.U.H. is not effi-

cient in functional bleeding, frequent curetting often helps, and eventually a proper rhythm is resumed. If hormone treatment and curettage fail, hysterectomy is the method of choice in women between the ages of thirty-five and forty-five, and radium and x-ray treatment in older women. Hysterectomy is advocated in young women because ovaries can be left and normal function will occur until the patient's menopause arrives. This has been shown to be five years or more in a large majority of cases. Removal of the uterus does not injure the ovaries, and they will continue to function normally if their blood supply is not interfered with, but tension on the ovarian artery must be avoided.

Postmenopausal bleeding means cancer in all cases until proved otherwise. Careful curettage and microscopic examination of the curettings are absolutely necessary. The peritoneoscope may be used to determine the presence or absence of ovarian or tubal tumors. The commonest causes of such bleeding are cervical and endometrial cancer, but tumors of the ovary, both benign and malignant, may be responsible, as may polyps of the cervix or endometrium. It is unwise to give radium to women who bleed after the menopause until the actual cause of the bleeding has been determined. Radium often causes obliteration of the uterine cavity, and endometrial cancer in the region of a cornu, or undiagnosed ovarian or tubal tumors, may grow until cure is out of the question. In unexplained postmenopausal bleeding it is best to wait after a curettage. If bleeding does not take place, well and good, if it does, surgical and not radiological treatment is best.

## SURGICAL PROCEDURES

Most advances in surgery have to do with uterine prolapse. There are numerous methods of treatment, and the best method for the individual case must be selected. The newest procedure of merit being popularized in this country is the so-called Fothergill or Manchester operation, which tightens the cardinal ligaments of the uterus. This operation, first done by Donald, of Manchester, England, and later described by Fothergill, is very popular in the north of England. It is based on the anatomical theory that the cardinal ligaments (those tissues at the base of the broad ligament which contain the uterine arteries, veins, nerves and connective tissue) are the main support of the uterus. It is always noted in doing a vaginal hysterectomy that section of these ligaments releases the uterus. They are its main support. This operation consists in denuding the anterior vaginal wall and pushing back the bladder. Deep sutures are taken in the tissue to the

outer side of the cervix, and are then carried over the cervix and into the corresponding tissue of the opposite side. They are tied tightly in front of the cervix. Pulling these tissues together in front of the cervix pushes it back and the body of the uterus up. If three or four sutures are inserted and tied, prolapse is relieved and retroversion reduced. This is especially noticeable when the ligaments retreat. The operation successfully accomplishes its aim. In addition to the cardinal ligament sutures, the fascia of the anterior vaginal wall is sutured over the bulging bladder and the thick pubocervical fascia is anchored higher up on the cervix. The perineum is then repaired in the usual manner. This operation is easy to do, takes very little time and is successful in most cases. It can be used with or without amputation of the cervix, but usually the cervix is removed. It is said by the Manchester group that pregnancy is not interfered with—or very little, if the cervix is not amputated—and that therefore sterilization is not necessary. The operation can be done in a younger age group than can the interposition operation.

In old women, unmarried women or those who are not good risks for the extensive surgery, the La Fort operation is popular. This consists of the removal of a rectangle from the anterior and posterior vaginal walls. The two raw surfaces are sutured together over the cervix, which may or may not be amputated. The last line of sutures is just below the urethra and at the perineal outlet. Thus tubes which reach to the cervix for drainage are left on either side of the vagina. This operation partially closes the vagina and prevents satisfactory intercourse. The perineum is then repaired in the usual fashion.

Patients with cystocele and prolapse who need abdominal surgery for tumors or cysts or adnexal disease are best treated by total abdominal hysterectomy. Such an operation, combined with removal of as much anterior vaginal wall as is needed from the inside, relieves the cystocele and prolapse. The perineum is then repaired in the usual manner, this is essential because proper support is necessary for the thinned-out pelvic floor.

Cancer of the cervical stump is an ever-present danger in patients who have had a supravaginal hysterectomy. No method of treatment of the cervix, except perhaps high amputation, will prevent the occurrence of cervical cancer. There is nothing so discouraging as the appearance of a lesion which might have been prevented had the cervix been removed.

Total hysterectomy done carefully and with due regard to bladder and ureters should not be much

more dangerous, except for sepsis, than the supravaginal operation. The technic must be perfected and the operation done without much trauma or hemorrhage. If vaginal plastic operations are to be done it is best to do the abdominal part of the operation first and later repair the urethrocele or perineum. An important technical step in the prevention of sepsis is first to remove the appendix, so that after the vagina is opened the upper abdomen need not be explored again.

The results following the treatment of cancer of the vulva have been improved by the use of the Bassett operation. This procedure includes complete vulvectomy, with deep and superficial dissection of the inguinal and femoral lymph-node areas. Previous results have been poor, but with radical dissection of the groins a marked improvement has occurred. The external iliac nodes, the deep and superficial femoral and inguinal nodes and Cloquet's node, which lies under Poupart's ligament near the femoral canal, must all be removed. It is safest not to do the whole operation in one stage. The vulvectomy should be done first, followed later by dissection of the groins. Silk ligatures should be employed throughout and the wounds should not be drained. A plaster spica or a spica of elastic bandages should be used so as to allow the patient as little motion as possible. In this way lymphorrhea and groin infections are avoided.

Repair of the urethra for incontinence of urine demands a wide denudation of the tissues surrounding the urethra. It should be bared 4 cm from its orifice. As a result of lacerations, there is usually scar formation on one side or the other of the urethral support from the symphysis. The incising of these scars and the suture of the laceration reconstruct the normal support of the urethra. It is easy to plicate and pucker in the bulging urethra with sutures of fine silk. Catgut knots are large and interfere with each other, but silk ties are small and multiple layers can be introduced without difficulty. Silk sutures do not act as foreign bodies and do not cause sinuses and slough. Silk is a great addition to the technic of the repair of the urethra.

Suspensions of the uterus are less and less frequently done. Retroversion may be a perfectly normal development and an attempt to suspend it may be followed by recurrence, because retroversion is the proper position of the uterus, it is frequent, and few patients have symptoms. It is infrequently a cause of primary sterility, and during pregnancy the uterus is rarely incarcerated. There are certain cases where retroversion should be corrected—a few sterile patients, and some with

## DYSMENORRHEA

The treatment of dysmenorrhea by means of hormones is disappointing, but before long a treatment may be evolved that will do away with surgery. Dilatation of the cervix is not satisfactory, but should be done before resection of the presacral nerve or superior hypogastric neurectomy. There is no doubt of the efficiency of the latter operation, for successful cases have been reported where it has been done without other operative procedures. The success of neurectomy is reported as 75 to 85 per cent, and such results are satisfactory for any operative procedure. The operation is not dangerous but is painstaking and difficult, and all the superior hypogastric plexus must be removed to assure success. Coitus is satisfactory following the operation, and pregnancy occurs in a high percentage of cases. In some patients labor pains are eliminated during delivery.

## THE MENOPAUSE

The treatment of the menopause by estrin is most satisfactory. The hormone can be given by intramuscular injection, by mouth or by vaginal suppository. It is decidedly more efficacious by injection, but oral administration is good. The proper way to treat patients is to give large doses (10,000 rat units) biweekly at first, and to cut the dosage down as low as possible when relief is obtained. Estrin is helpful in premenstrual tension, dysmenorrhea, night sweats, dizziness and even in involutional melancholia. There is no doubt as to its worth in various complaints of women at the menopause.

## MENSTRUAL DISTURBANCE

Disturbance of the menstrual rhythm, such as too frequent periods and delayed periods, are usually due to early or late ovulation. In some instances ovulation does not take place for a month, and in that case the period should come two weeks later, or in six weeks. This has been proved many times by weekly endometrial biopsies. In some women there is no ovulation rhythm and therefore their periods have no regularity, but arrive two weeks after each ovulation. This peculiarity does not mean lack of fertility, but it is difficult to advise such patients as to when ovulation takes place.

Pregnancy urine hormone is still of value in the treatment of abnormal bleeding. Progesterin and testosterone (testicular hormone) are advocated, and in some clinics good results are being obtained. The latter methods are expensive, as large doses are necessary and at the present time the cost is prohibitive. If the P.U.H. is not effi-

cacious in functional bleeding, frequent curetting often helps, and eventually a proper rhythm is resumed. If hormone treatment and curettage fail, hysterectomy is the method of choice in women between the ages of thirty-five and forty five, and radium and x-ray treatment in older women. Hysterectomy is advocated in young women because ovaries can be left and normal function will occur until the patient's menopause arrives. This has been shown to be five years or more in a large majority of cases. Removal of the uterus does not injure the ovaries, and they will continue to function normally if their blood supply is not interfered with, but tension on the ovarian artery must be avoided.

Postmenopausal bleeding means cancer in all cases until proved otherwise. Careful curettage and microscopic examination of the curettings are absolutely necessary. The peritoneoscope may be used to determine the presence or absence of ovarian or tubal tumors. The commonest causes of such bleeding are cervical and endometrial cancer, but tumors of the ovary, both benign and malignant, may be responsible, as may polyps of the cervix or endometrium. It is unwise to give radium to women who bleed after the menopause until the actual cause of the bleeding has been determined. Radium often causes obliteration of the uterine cavity, and endometrial cancer in the region of a cornu, or undiagnosed ovarian or tubal tumors, may grow until cure is out of the question. In unexplained postmenopausal bleeding it is best to wait after a curettage. If bleeding does not take place, well and good, if it does, surgical and not radiological treatment is best.

## SURGICAL PROCEDURES

Most advances in surgery have to do with uterine prolapse. There are numerous methods of treatment, and the best method for the individual case must be selected. The newest procedure of merit being popularized in this country is the so-called Fothergill or Manchester operation, which tightens the cardinal ligaments of the uterus. This operation, first done by Donald, of Manchester, England, and later described by Fothergill, is very popular in the north of England. It is based on the anatomical theory that the cardinal ligaments (those tissues at the base of the broad ligament which contain the uterine arteries, veins, nerves and connective tissue) are the main support of the uterus. It is always noted in doing a vaginal hysterectomy that section of these ligaments releases the uterus. They are its main support. This operation consists in denuding the anterior vaginal wall and pushing back the bladder. Deep sutures are taken in the tissue to the

outer side of the cervix, and are then carried over the cervix and into the corresponding tissue of the opposite side. They are tied tightly in front of the cervix. Pulling these tissues together in front of the cervix pushes it back and the body of the uterus up. If three or four sutures are inserted and tied, prolapse is relieved and retroversion reduced. This is especially noticeable when the ligaments retreat. The operation successfully accomplishes its aim. In addition to the cardinal ligament sutures, the fascia of the anterior vaginal wall is sutured over the bulging bladder and the thick pubocervical fascia is anchored higher up on the cervix. The perineum is then repaired in the usual manner. This operation is easy to do, takes very little time and is successful in most cases. It can be used with or without amputation of the cervix, but usually the cervix is removed. It is said by the Manchester group that pregnancy is not interfered with—or very little, if the cervix is not amputated—and that therefore sterilization is not necessary. The operation can be done in a younger age group than can the interposition operation.

In old women, unmarried women or those who are not good risks for the extensive surgery, the La Fort operation is popular. This consists of the removal of a rectangle from the anterior and posterior vaginal walls. The two raw surfaces are sutured together over the cervix, which may or may not be amputated. The last line of sutures is just below the urethra and at the perineal outlet. Thus tubes which reach to the cervix for drainage are left on either side of the vagina. This operation partially closes the vagina and prevents satisfactory intercourse. The perineum is then repaired in the usual fashion.

Patients with cystocele and prolapse who need abdominal surgery for tumors or cysts or adnexal disease are best treated by total abdominal hysterectomy. Such an operation, combined with removal of as much anterior vaginal wall as is needed from the inside, relieves the cystocele and prolapse. The perineum is then repaired in the usual manner, this is essential because proper support is necessary for the thinned-out pelvic floor.

Cancer of the cervical stump is an ever-present danger in patients who have had a supravaginal hysterectomy. No method of treatment of the cervix, except perhaps high amputation, will prevent the occurrence of cervical cancer. There is nothing so discouraging as the appearance of a lesion which might have been prevented had the cervix been removed.

Total hysterectomy done carefully and with due regard to bladder and ureters should not be much

more dangerous, except for sepsis, than the supravaginal operation. The technic must be perfected and the operation done without much trauma or hemorrhage. If vaginal plastic operations are to be done it is best to do the abdominal part of the operation first and later repair the urethrocele or perineum. An important technical step in the prevention of sepsis is first to remove the appendix, so that after the vagina is opened the upper abdomen need not be explored again.

The results following the treatment of cancer of the vulva have been improved by the use of the Bassett operation. This procedure includes complete vulvectomy, with deep and superficial dissection of the inguinal and femoral lymph-node areas. Previous results have been poor, but with radical dissection of the groins a marked improvement has occurred. The external iliac nodes, the deep and superficial femoral and inguinal nodes and Cloquet's node, which lies under Poupert's ligament near the femoral canal, must all be removed. It is safest not to do the whole operation in one stage. The vulvectomy should be done first, followed later by dissection of the groins. Silk ligatures should be employed throughout and the wounds should not be drained. A plaster spica or a spica of elastic bandages should be used so as to allow the patient as little motion as possible. In this way lymphorrhea and groin infections are avoided.

Repair of the urethra for incontinence of urine demands a wide denudation of the tissues surrounding the urethra. It should be bared 4 cm from its orifice. As a result of lacerations, there is usually scar formation on one side or the other of the urethral support from the symphysis. The incising of these scars and the suture of the laceration reconstruct the normal support of the urethra. It is easy to plicate and pucker in the bulging urethra with sutures of fine silk. Catgut knots are large and interfere with each other, but silk ties are small and multiple layers can be introduced without difficulty. Silk sutures do not act as foreign bodies and do not cause sinuses and slough. Silk is a great addition to the technic of the repair of the urethra.

Suspensions of the uterus are less and less frequently done. Retroversion may be a perfectly normal development and an attempt to suspend it may be followed by recurrence, because retroversion is the proper position of the uterus, it is frequent, and few patients have symptoms. It is infrequently a cause of primary sterility, and during pregnancy the uterus is rarely incarcerated. There are certain cases where retroversion should be corrected—a few sterile patients, and some with

dysmenorrhea, especially the type occurring following childbirth, with a uterus that cannot be held up by pessary. Suspension should nearly always be done following operations on the tubes and ovaries, especially in pelvic inflammations or endometriosis. This operation should not be a fixation of any structure but should be a suspension that leaves the uterus freely movable. In most cases of retroversion the Baldy-Webster or the Coffey operation is best. There must be a good reason for a uterine suspension, and with more understanding the reasons are becoming fewer.

#### MISCELLANEOUS

Pain in the pelvis due to recurrent cancer, provided it is not due to lesions of the kidney, is well controlled for weeks to months by the injection of absolute alcohol intraspinaly. This can be done in two ways: with the patient on her side and hips raised and the injection made first for one side of the cord and later for the other, or with the patient lying on a table with the buttocks up and the head and feet down. By this method both sides of the cord are anesthetized at the same time. If the pain is not relieved by injection, cordotomy, either unilateral or bilateral, may be done. Cordotomy gives permanent relief but removes the sense of temperature as well as pain. As in alcohol injection, pain due to kidney disease is not relieved.

In cancer of the cervix it is important to determine the condition of the kidneys before, during

and after radiation. There can be no doubt that many patients have died of uremia who might have been saved by prompt and intelligent urological treatment. Pain due to renal difficulty may be of any type and in any part of the lower abdomen or thighs. Recognition and treatment of blocked ureters and hydronephroses by dilatation of the ureter or nephrostomy will relieve pain almost instantaneously.

The Gellhorn pessary, which is mushroom shaped and can be removed and replaced by the patient, has proved of great value in the treatment of prolapse, with or without cystocele and rectocele. The mushroom top is cupped and this causes a moderate amount of suction, so that a small pessary can be used. The handle (the stem of the mushroom) makes it easy for the patient to remove and replace the pessary, and also helps to keep it high up in the vagina, especially when sitting.

#### SUMMARY

A brief review of many of the recent advances in gynecology has been presented. They have been briefly described, but further reading on each subject will be necessary to appreciate them fully. Other probable advances have been omitted, since they have not, as yet, been proved to be of practical value.

Surgery, radiology and hormonology apparently constitute the specialty of gynecology.

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED  
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., *Editor*

### CASE 25061

#### PRESENTATION OF CASE

A forty-seven-year-old American housewife entered complaining of a brown vaginal discharge of six weeks' duration.

Four years prior to admission she had had a miscarriage during the third month of pregnancy. Following this the duration of the periods increased from five to seven days and the flow became much more profuse. However, her catamenia remained regular, with no staining or discharge between menses. Six weeks before entry she missed her regular period and noticed instead the beginning of a brown vaginal discharge. This continued for a month with the exception of cessation for a few days following treatment with douches. Two weeks before admission there was a discharge of bright-red blood which lasted all day but it did not resemble the normal menstrual flow. The brownish discharge again followed, continuing to the day of entry. The discharge was never profuse, and she had not felt faint. Six days before entry she noted the onset of mild cramp-like pains in the lower abdomen. They were felt on both sides and occurred intermittently. Three days later they became more severe and resembled labor pains, starting in the back and radiating around to the midlower abdomen, almost reaching the stage of "bearing down" pains. During these last six weeks she had noticed slight nausea and her breasts had become somewhat painful.

She had diabetes, discovered four months prior to entry. She had had nine pregnancies, and seven children living and well.

Physical examination showed an obese woman. Examination of the chest was negative. The blood pressure was 130 systolic, 85 diastolic. In the midlower abdomen a firm, tender, symmetrical mass that extended to within 1 cm. of the umbilicus was palpated. It resembled a uterus in the sixth month of pregnancy. Pelvic examination showed that the cervical os pointed posteriorly. The mass mentioned was freely mobile and attached to the cervix. The cervix was firm, not soft or patulous. After palpation the cervix began bleeding profusely.

The temperature was 99°F, the pulse 85, the respirations 20.

The urine examination showed a trace of albumin and innumerable red blood cells. The blood showed a red-cell count of 3,310,000 with 72 per cent hemoglobin, and a white-cell count of 14,600. A blood Hinton test was negative.

On the day after admission the patient lost 1500 cc. of blood by vagina. The blood pressure neared shock levels before transfusion brought relief. On the second hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. JOE V. MEIGS: This case is a great puzzle to me. There are so many possible diagnoses that it is very difficult to limit it to any one. When a woman bleeds at the age of forty-seven for six weeks and has a brownish discharge one wants to know whether it is really blood or just a discharge. I take it in this case that it was blood. She had had a miscarriage four years before, when forty-three years old. Following this her periods increased so that they lasted from five to seven days, and the bleeding became profuse. As a woman reaches the menopause, her periods frequently increase in duration and amount, however, sometimes the reverse is true.

"Six weeks before entry she missed her regular period and noticed instead the beginning of a brown vaginal discharge." I do not know exactly what that means—whether she went six weeks and then a discharge started up or whether she missed the period and started to bleed. If she skipped a period it might mean one thing, if she bled abnormally at the regular time it might mean something else. The facts that she had labor pains and was nauseated, that she had changes in the breasts and that the uterus was in the midline, symmetrical and consistent with pregnancy make one think, coupled with her history, that she had an abnormal pregnancy of some sort. On the other hand, patients approaching the menopause do have changes in their breasts, and we have noticed in the Endocrine Clinic here and at the Huntington Memorial Hospital that many patients at this time commence to have discomfort and pain in the breasts. The facts that the cervix was firm and hard and not patulous and that she was bleeding make one wonder if she was miscarrying the abnormal pregnancy. However, I think that this particular observation may not have been correct. The cervix may have been softer than normal and still have felt fairly firm. The question as to why the cervix should have bled after palpation I cannot answer. One thinks of carcinoma of the cervix, but the history would have been more obvious.

dysmenorrhea, especially the type occurring following childbirth, with a uterus that cannot be held up by pessary. Suspension should nearly always be done following operations on the tubes and ovaries, especially in pelvic inflammations or endometriosis. This operation should not be a fixation of any structure but should be a suspension that leaves the uterus freely movable. In most cases of retroversion the Baldy-Webster or the Coffey operation is best. There must be a good reason for a uterine suspension, and with more understanding the reasons are becoming fewer.

#### MISCELLANEOUS

Pain in the pelvis due to recurrent cancer, provided it is not due to lesions of the kidney, is well controlled for weeks to months by the injection of absolute alcohol intraspinally. This can be done in two ways: with the patient on her side and hips raised and the injection made first for one side of the cord and later for the other, or with the patient lying on a table with the buttocks up and the head and feet down. By this method both sides of the cord are anesthetized at the same time. If the pain is not relieved by injection, cordotomy, either unilateral or bilateral, may be done. Cordotomy gives permanent relief but removes the sense of temperature as well as pain. As in alcohol injection, pain due to kidney disease is not relieved.

In cancer of the cervix it is important to determine the condition of the kidneys before, during

and after radiation. There can be no doubt that many patients have died of uremia who might have been saved by prompt and intelligent urological treatment. Pain due to renal difficulty may be of any type and in any part of the lower abdomen or thighs. Recognition and treatment of blocked ureters and hydronephroses by dilatation of the ureter or nephrostomy will relieve pain almost instantaneously.

The Gellhorn pessary, which is mushroom shaped and can be removed and replaced by the patient, has proved of great value in the treatment of prolapse, with or without cystocele and rectocele. The mushroom top is cupped and thus causes a moderate amount of suction, so that a small pessary can be used. The handle (the stem of the mushroom) makes it easy for the patient to remove and replace the pessary, and also helps to keep it high up in the vagina, especially when sitting.

#### SUMMARY

Six weeks before entry she missed her regular period and noticed instead the beginning of a brown vaginal discharge. This continued for a month with the exception of cessation for a few days following treatment with douches. Two weeks before admission there was a discharge of bright-red blood which lasted all day but it did not resemble the normal menstrual flow. The brownish discharge again followed, continuing to the day of entry. The discharge was never profuse, and she had not felt faint. Six days before entry she noted the onset of mild cramp-like pains in the lower abdomen. They were felt on both sides and occurred intermittently. Three days later they became more severe and resembled labor pains, starting in the back and radiating around to the midlower abdomen, almost reaching the stage of "bearing down" pains. During these last six weeks she had noticed slight nausea and her breasts had become somewhat painful.

She had diabetes, discovered four months prior to entry. She had had nine pregnancies, and seven children living and well.

Physical examination showed an obese woman. Examination of the chest was negative. The blood pressure was 130 systolic, 85 diastolic. In the midlower abdomen a firm, tender, symmetrical mass that extended to within 1 cm. of the umbilicus was palpated. It resembled a uterus in the sixth month of pregnancy. Pelvic examination showed that the cervical os pointed posteriorly. The mass mentioned was freely mobile and attached to the cervix. The cervix was firm, not soft or patulous. After palpation the cervix began bleeding profusely.

The temperature was 99°F, the pulse 85, the respirations 20.

The urine examination showed a trace of albumin and innumerable red blood cells. The blood showed a red-cell count of 3,310,000 with 72 per cent hemoglobin, and a white-cell count of 14,600. A blood Hinton test was negative.

On the day after admission the patient lost 1500 cc. of blood by vagina. The blood pressure neared shock levels before transfusion brought relief. On the second hospital day an operation was performed.

### DIFFERENTIAL DIAGNOSIS

DR. JOE V. MEIGS: This case is a great puzzle to me. There are so many possible diagnoses that it is very difficult to limit it to any one. When a woman bleeds at the age of forty-seven for six weeks and has a brownish discharge one wants to know whether it is really blood or just a discharge. I take it in this case that it was blood. She had had a miscarriage four years before, when forty-three years old. Following this her periods increased so that they lasted from five to seven days, and the bleeding became profuse. As a woman reaches the menopause, her periods frequently increase in duration and amount, however, sometimes the reverse is true.

"Six weeks before entry she missed her regular period and noticed instead the beginning of a brown vaginal discharge." I do not know exactly what that means—whether she went six weeks and then a discharge started up or whether she missed the period and started to bleed. If she skipped a period it might mean one thing, if she bled abnormally at the regular time it might mean something else. The facts that she had labor pains and was nauseated, that she had changes in the breasts and that the uterus was in the midline, symmetrical and consistent with pregnancy make one think, coupled with her history, that she had an abnormal pregnancy of some sort. On the other hand, patients approaching the menopause do have changes in their breasts, and we have noticed in the Endocrine Clinic here and at the Huntington Memorial Hospital that many patients at this time commence to have discomfort and pain in the breasts. The facts that the cervix was firm and hard and not patulous and that she was bleeding make one wonder if she was miscarrying the abnormal pregnancy. However, I think that this particular observation may not have been correct. The cervix may have been softer than normal and still have felt fairly firm. The question as to why the cervix should have bled after palpation I cannot answer. One thinks of carcinoma of the cervix, but the history would have been more obvious.

dysmenorrhea, especially the type occurring following childbirth, with a uterus that cannot be held up by pessary. Suspension should nearly always be done following operations on the tubes and ovaries, especially in pelvic inflammations or endometriosis. This operation should not be a fixation of any structure but should be a suspension that leaves the uterus freely movable. In most cases of retroversion the Baldy-Webster or the Coffey operation is best. There must be a good reason for a uterine suspension, and with more understanding the reasons are becoming fewer.

#### MISCELLANEOUS

Pain in the pelvis due to recurrent cancer, provided it is not due to lesions of the kidney, is well controlled for weeks to months by the injection of absolute alcohol intraspinally. This can be done in two ways: with the patient on her side and hips raised and the injection made first for one side of the cord and later for the other, or with the patient lying on a table with the buttocks up and the head and feet down. By this method both sides of the cord are anesthetized at the same time. If the pain is not relieved by injection, cordotomy, either unilateral or bilateral, may be done. Cordotomy gives permanent relief but removes the sense of temperature as well as pain. As in alcohol injection, pain due to kidney disease is not relieved.

In cancer of the cervix it is important to determine the condition of the kidneys before, during

and after radiation. There can be no doubt that many patients have died of uremia who might have been saved by prompt and intelligent urological treatment. Pain due to renal difficulty may be of any type and in any part of the lower abdomen or thighs. Recognition and treatment of blocked ureters and hydronephroses by dilatation of the ureter or nephrostomy will relieve pain almost instantaneously.

The Gellhorn pessary, which is mushroom shaped and can be removed and replaced by the patient, has proved of great value in the treatment of prolapse, with or without cystocele and rectocele. The mushroom top is cupped and thus causes a moderate amount of suction, so that a small pessary can be used. The handle (the stem of the mushroom) makes it easy for the patient to remove and replace the pessary, and also helps to keep it high up in the vagina, especially when sitting.

#### SUMMARY

A brief review of many of the recent advances in gynecology has been presented. They have been briefly described, but further reading on each subject will be necessary to appreciate them fully. Other probable advances have been omitted, since they have not, as yet, been proved to be of practical value.

Surgery, radiology and hormonology apparently constitute the specialty of gynecology.

### CASE 25061

#### PRESENTATION OF CASE

A forty-seven-year-old American housewife entered complaining of a brown vaginal discharge of six weeks' duration.

Four years prior to admission she had had a miscarriage during the third month of pregnancy. Following this the duration of the periods increased from five to seven days and the flow became much more profuse. However, her catamenia remained regular, with no staining or discharge between menses. Six weeks before entry she missed her regular period and noticed instead the beginning of a brown vaginal discharge. This continued for a month with the exception of cessation for a few days following treatment with douches. Two weeks before admission there was a discharge of bright-red blood which lasted all day but it did not resemble the normal menstrual flow. The brownish discharge again followed, continuing to the day of entry. The discharge was never profuse, and she had not felt faint. Six days before entry she noted the onset of mild cramp-like pains in the lower abdomen. They were felt on both sides and occurred intermittently. Three days later they became more severe and resembled labor pains, starting in the back and radiating around to the midlower abdomen, almost reaching the stage of "bearing down" pains. During these last six weeks she had noticed slight nausea and her breasts had become somewhat painful.

She had diabetes, discovered four months prior to entry. She had had nine pregnancies, and seven children living and well.

Physical examination showed an obese woman. Examination of the chest was negative. The blood pressure was 130 systolic, 85 diastolic. In the midlower abdomen a firm, tender, symmetrical mass that extended to within 1 cm. of the umbilicus was palpated. It resembled a uterus in the sixth month of pregnancy. Pelvic examination showed that the cervical os pointed posteriorly. The mass mentioned was freely mobile and attached to the cervix. The cervix was firm, not soft or patulous. After palpation the cervix began bleeding profusely.

The temperature was 99°F., the pulse 85, the respirations 20.

The urine examination showed a trace of albumin and innumerable red blood cells. The blood showed a red-cell count of 3,310,000 with 72 per cent hemoglobin, and a white-cell count of 14,600. A blood Hinton test was negative.

On the day after admission the patient lost 1500 cc. of blood by vagina. The blood pressure neared shock levels before transfusion brought relief. On the second hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. JOE V. MEIGS. This case is a great puzzle to me. There are so many possible diagnoses that it is very difficult to limit it to any one. When a woman bleeds at the age of forty-seven for six weeks and has a brownish discharge one wants to know whether it is really blood or just a discharge. I take it in this case that it was blood. She had had a miscarriage four years before, when forty-three years old. Following this her periods increased so that they lasted from five to seven days, and the bleeding became profuse. As a woman reaches the menopause, her periods frequently increase in duration and amount, however, sometimes the reverse is true.

"Six weeks before entry she missed her regular period and noticed instead the beginning of a brown vaginal discharge." I do not know exactly what that means, whether she went six weeks and then a discharge started up or whether she missed the period and started to bleed. If she skipped a period it might mean one thing, if she bled abnormally at the regular time it might mean something else. The facts that she had labor pains and was nauseated, that she had changes in the breasts and that the uterus was in the midline, symmetrical and consistent with pregnancy make one think, coupled with her history, that she had an abnormal pregnancy of some sort. On the other hand, patients approaching the menopause do have changes in their breasts, and we have noticed in the Endocrine Clinic here and at the Huntington Memorial Hospital that many patients at this time commence to have discomfort and pain in the breasts. The facts that the cervix was firm and hard and not patulous and that she was bleeding make one wonder if she was miscarrying the abnormal pregnancy. However, I think that this particular observation may not have been correct. The cervix may have been softer than normal and still have felt fairly firm. The question as to why the cervix should have bled after palpation I cannot answer. One thinks of carcinoma of the cervix, but the history would have been more obvious.

if she had had cancer, and the cervix would have been friable rather than as it is described here. The uterus, moreover, is much larger and has apparently grown faster than can be accounted for by a diagnosis of cervical cancer.

On the day after admission the patient lost 1500 cc of blood which must mean that she had a very severe hemorrhage. I recall no patient with bleeding from fibroids of any type that lost that much blood in such a short time. A submucous fibroid possibly could bleed that hard, but it seems improbable. Sarcoma would account for a rapidly enlarging uterus, but again I doubt if it would produce so severe a hemorrhage as this was.

I believe that she had an abnormal pregnancy, probably a hydatid mole, possibly a chorionepithelioma, or that she had a submucous fibroid with carcinoma of the cervix. I think the first is the correct diagnosis.

#### CLINICAL DISCUSSION

DR. ROBERT LINTON: Dr Meigs has done a splendid job, as hydatid mole was the correct diagnosis. We had the additional advantage of observing some of the grape-like material that came out of the cervix just before operation.

DR. MEIGS: I should like to know whether an Aschheim-Zondek test was done.

DR. TRACY B. MALLORY: The Aschheim-Zondek report came back the day after operation. It was reported as positive. Their hand, of course, was forced and they could not delay operation.

DR. MEIGS: I have never seen anyone bleed so severely as this from a fibroid, this made me believe that it must have been an abnormal pregnancy. The fact that she had apparently skipped a period and the size of the uterus made me wonder about mole. The uterus was the size of a six months' pregnancy in a very short time.

DR. LANGDON PARSONS: She had a pregnancy at forty-three. Is it not true that chorionepithelioma at this age is not uncommon?

DR. MEIGS: Yes, furthermore, we have heard of cases developing as long as eight years after pregnancy.

DR. LINTON: I think the question of treatment is interesting. There was a good deal of discussion at the time. I was afraid to curet her because she had lost so much blood following pelvic examinations and I thought I would not be able to control the bleeding. Therefore I elected to do a total hysterectomy.

DR. MEIGS: It was a mole and not an epithelioma?

DR. LINTON: Yes.

DR. MALLORY: Dr. Thomas R. Goethals

opinion was asked and he advised hysterectomy rather than an attempt to empty the uterus.

I remember one case we had at postmortem in which there was said to have been a fatal hemorrhage from fibroids. However, we did not have an adequate history, so we did not know how long she had bled or how profuse the single hemorrhage had been.

DR. MEIGS: Such patients are apt to bleed a large amount over a long period of time but not suddenly.

#### CLINICAL DIAGNOSIS

Hydatid mole

#### DR. MEIGS'S DIAGNOSIS

Hydatid mole (? chorionepithelioma)

Submucous fibroid, with carcinoma of the cervix?

#### ANATOMICAL DIAGNOSIS

Hydatid mole

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: The mole we found in the uterus consisted of grape-like cysts and grossly was quite benign looking. Histologically there was, as is often the case, a considerable degree of activity that makes one wonder a little whether it might not have been malignant. In any case of this sort the patient should be kept under observation and repeated Aschheim-Zondek tests should be done at frequent intervals. There are very few pathologists with sufficient experience in this field to warrant complete confidence in their ability to rule out cancer in such a case.

DR. MEIGS: Were there any lutein cysts in the ovary?

DR. MALLORY: None were noted.

#### CASE 25062

#### PRESENTATION OF CASE

A forty-three-year-old, married American automobile salesman was admitted complaining of right-sided abdominal pain.

Fifteen months before entry the patient had experienced a sudden, sharp knife-like pain in his abdomen immediately to the right of the umbilicus, which radiated toward the right side. The pain lasted for an hour and was sufficiently intense to cause him to lie down. During the next ten months somewhat similar attacks had occurred, gradually increasing in severity and frequency until at the end of this period he was having three to four such attacks each month. Most of them began in the right lower quadrant as a persistent

soreness, occurred usually in the evening and disappeared the following morning with the aid of ice-packs. After the first attack the pain was of a constant boring nature. It did not radiate and was not accompanied by gastrointestinal upsets, with the exception of slight nausea. He vomited on only one occasion. At the end of the tenth month he had had attacks on two successive days, was thought to have had appendicitis and had come to the Emergency Ward of this hospital. Physical examination showed only slight tenderness over the right abdomen. There were no positive laboratory findings. He was discharged home and told to return if the symptoms recurred. Following this he had had frequent attacks of cramp-like right lower abdominal pain but continued to work, although it was occasionally necessary for him to return home to rest and apply an icebag. The pain varied in its time of appearance but most commonly occurred three to four hours after a meal. Food and antacids occasionally gave partial relief. Vomiting resulted in the improvement of symptoms, but the only reliable treatment was rest and icepacks. Motion increased the pain. Five weeks before entry he vomited one of his meals as essentially unchanged food. During these five weeks he vomited on fifteen or twenty occasions. The vomitus did not contain blood or coffee-grounds material. During the previous few weeks the pain became constant. Four weeks prior to admission he again entered the Emergency Ward, stating that he had been in bed for the past thirty-six hours with right-lower-quadrant pain and had vomited twice. He had lost 8 pounds in weight since his discharge. Physical examination was negative. The blood showed a white-cell count of 16,800. After careful questioning he stated that his pain started in the right costovertebral angle and radiated around to the right lower quadrant. An intravenous pyelogram, Graham test and barium enema were negative. The following day he was much improved and was again discharged. Following this he stated that he had felt a small lump 3 or 4 cm in diameter in his abdomen immediately to the right of the umbilicus. Eleven days before admission the patient again came to the Emergency Ward stating that he had been having intermittent pain beginning in the right costovertebral angle and radiating toward the pubis. Physical examination was again entirely negative. A gastrointestinal x-ray series was done, which showed a 4 cm ulcer crater, 2 cm deep, on the lesser curvature of the stomach, just above the antrum. Belladonna and dietary therapy prevented vomiting during the few days before admission to the wards, but the pain continued. During his entire illness,

though slightly constipated, he had not noticed black, clay-colored or tarry stools. He was an inveterate smoker and drank a considerable amount of coffee and tea. He also had had many financial worries. His past and family histories were otherwise noncontributory.

Physical examination revealed a thin, undernourished male. Small, firm, movable, cervical and axillary nodes were palpated. The chest examination was negative. The blood pressure was 132 systolic, 90 diastolic. There was tenderness in the epigastrium, and spasm, which was apparently voluntary. No masses could be palpated. There was no costovertebral tenderness. Rectal examination revealed tenderness and dullness high on the right. The extremities were negative.

The temperature was 99.8°F., the pulse 90 and the respirations 15.

The urine examination was negative. The blood showed a red-cell count of 3,950,000, with 87 per cent hemoglobin, and a white-cell count of 8100 with 77 per cent polymorphonuclears. The non-protein nitrogen of the serum was 27 mg per cent, the carbon-dioxide combining power 57.6 vol, and the protein 6.8 gm. The chlorides were equivalent to 96 cc of N/10 sodium chloride. A blood Wassermann test was negative. A gastric analysis showed 24 units of free acid and 38 units of total acid, following histamine, 62 units of free acid and 70 units of total acid, and one hour following the injection, 106 units of free acid and 110 units of total acid. The gastric juice was water-clear, except for a small amount of bile-tinged, mucoid sediment. Four stool examinations were guaiac positive.

On the sixth hospital day a gastroscopic examination was done. A large ulcer approximately 3 cm in diameter and 1 cm in depth was seen on the lesser curvature. The margins were nodular, and the base was covered with barium and blood clot. The surrounding mucosa was nodular.

On the twelfth hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. RICHARD H. WALLACE. The history of pain in this case is certainly inconsistent and bizarre. At one time or another the pain suggests a lesion in a good many different places in the abdomen. For instance, fifteen months before entry he had sudden, sharp, knife-like pains which radiated to his right side and were debilitating. These attacks of pain which increased in severity and frequency and were followed by persistent soreness, constant and boring in nature, in the right upper

quadrant, somewhat suggest gallstone colic. At least one attack, however, was thought to be acute appendicitis, because he was brought into the Emergency Ward with that diagnosis. Later he had cramp-like right lower abdominal pain, and then shortly after that, although there is no mention of epigastric pain, the pain came on three or four hours after meals and sometimes was relieved by food and antacids—which suggests gastric or duodenal ulcer. Then it is noted that motion increased the pain. That is a little suggestive of peritoneal irritation, perhaps inflammatory. Next, the pain instead of being intermittent became constant. It started at the right costovertebral angle and radiated around to the right lower quadrant. One might think of some renal lesion. Then the patient thought he noticed a lump 3 or 4 cm in diameter, but this was not confirmed on physical examination despite the fact that he was a thin undernourished man upon whom it was apparently possible to do a satisfactory abdominal examination. The pain again became intermittent and is described as beginning at the right costovertebral angle and radiating to the pubis, suggesting ureteral colic. All this is quite difficult for me to put together. We have two tangible leads—the x-ray study and the gastroscopic examination. I think we might see what the films show.

DR RICHARD SCHATZKI. A case like this means a lot of worry for the roentgenologist. You can see a large crater, but it is wider and not so deep as that in a case\* we discussed recently. In other words it is not so penetrating in character as the other crater. Furthermore, the surrounding induration is quite extensive, involving an area measuring 10 cm, so that the crater represents only a part of the diseased area. Unless one can demonstrate a definite tumor mass in such a case, I think it is fairly impossible to say from the x-ray whether the lesion is benign or malignant.

DR WALLACE. At least we have a definite lesion in the stomach. In regard to all the other suggestions,—gall-bladder disease, appendicitis and renal or ureteral stones,—there is very little else in the history or the findings to substantiate any of them. The pyelogram and the Graham tests were negative. The urine is reported as negative. I believe that we can rule out gross disease of that sort.

We come back to the old question, Is the lesion benign or malignant? From the history the type of pain is certainly not that of a gastric neoplasm. There is no mention of epigastric pain. There is a suggestion that the pain came on at a very definite period after meals and that it was re-

lieved by food and soda. The laboratory data add no helpful information until we get to the gastric analysis. That is certainly consistent with ulcer. We are reminded of the statement in the history that "he had had many financial worries," so there is considerable to make us believe that this may have been a benign ulcer.

On the other side of the fence the gastroscopic examination not only revealed the presence of the ulcer, as described by x-ray, but also showed that the ulcer margins and the surrounding mucosa were nodular. That definitely rules out benign ulcer, and so we must assume that we are dealing with a neoplasm of the stomach of some sort. Could this have been a leiomyosarcoma? I judged from reading the x-ray report that there was very little bulk to this tumor, but Dr Schatzki suggested that there may have been 10 cm of induration.

DR SCHATZKI. But not a real mass.

DR WALLACE. That, I believe, is against leiomyosarcoma. It is usually a bulky tumor and less likely to have ulceration of this sort. In the ones I have seen, the outstanding sign has been hemorrhage. We have very little to suggest that in the history, although there were four guaiac-positive stools. The vomitus had not been grossly bloody at any time, and I am inclined to rule out leiomyosarcoma. Some very rare type of sarcoma might explain the picture, but I do not know how one could make such a diagnosis. Certainly it is hard to rule out a carcinoma with central ulceration, though the one thing that makes me hesitate is the high acidity of the gastric contents. One usually expects an acidity in extensive cancer of the stomach. Certainly in a good many cases of cancer of the stomach there is a fairly normal acidity, but I believe it would be very unusual to have as high an acidity as this is.

I am interested in the small, fairly movable, cervical and axillary nodes mentioned in the physical examination. I do not imagine that they were biopsied or there probably would be some note of it. Although Dr Mallory has, at times, made the statement that in cases of gastrointestinal lymphoma the lymph nodes are likely to show no metastases, I still believe that lymphoma of the stomach might produce this picture. It is more likely to be associated with high acidity than is cancer, and might account for the fullness by rectum, although, of course, that might have been metastatic carcinoma. On the law of averages this ought to be a cancer of the stomach, but I am inclined to make my first choice lymphoma, with carcinoma of the stomach a close second.

DR EDWARD B BENEDICT. I did the gastroscopy on this patient, and from the size of the ulcer, the

irregular margins and the nodular appearance of the surrounding tissue, concluded my report by saying it was very suspicious of cancer. I have been fooled by a nodular appearance's being due to very marked hypertrophic gastritis, and therefore I was not sure about cancer. In making this differential diagnosis, Dr. Schindler, the inventor of the flexible gastroscope, believes that the presence of the circulating blood is very helpful in showing up the irregular outline of carcinoma, as distinguished from the smooth margin of benign ulcer, and that the gastroscopist studying the living tissue therefore has an advantage over the pathologist examining the gross specimen after removal. Only long experience will settle this point.

#### PREOPERATIVE DIAGNOSES

Benign gastric ulcer  
Carcinoma of stomach?

#### DR. WALLACE'S DIAGNOSIS

Lymphoma of stomach  
Carcinoma of stomach?

#### ANATOMICAL DIAGNOSIS

Carcinoma of stomach, with secondary peptic ulceration

#### PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: This stomach was resected with a clinical diagnosis of benign ulcer. When the specimen reached the laboratory we found a very extensive but rather shallow ulceration (Fig. 1). The borders were considerably undermined. The whole base of the ulcer showed the typical fibrinoid membrane of a peptic ulcer that is in the stage of acute progression, but on microscopical examination it was seen that there were atypical glands invading the submucosa. Each of several sections showed recognizable foci of

carcinoma at the margins of the ulcer. In other words cancer completely surrounded the area of ulceration so that the probabilities are again in favor, to my way of thinking, of an extensive car-

Figure 1 *Ulcerated Lesion at Lesser Curvature*

cinoma which had been almost completely eroded by a peptic ulcer.

DR. ALLEN G. BRAILEY: Was the nodular appearance due to cancer?

DR. MALLORY: It may have been, though we could not verify it. As Dr. Benedict says it may have been more obvious in life than it was after resection. We could not call this cancer from the gross examination in the laboratory, even by palpation, and I think you will agree that in the picture it looks perfectly benign.

DR. GRANTLEY W. TAYLOR: Did you find that stretch of 10 cm. of induration?

DR. MALLORY: There was a fairly extensive gastritis on both sides of the tumor, but we did not find any extensive tumor infiltration, in fact it was barely enough to establish the diagnosis.

quadrant, somewhat suggest gallstone colic. At least one attack, however, was thought to be acute appendicitis, because he was brought into the Emergency Ward with that diagnosis. Later he had cramp-like right lower abdominal pain, and then shortly after that, although there is no mention of epigastric pain, the pain came on three or four hours after meals and sometimes was relieved by food and antacids—which suggests gastric or duodenal ulcer. We could not call this cancer from the gross examination in the laboratory, even by palpation, and I think you will agree that in the picture it looks perfectly benign.

DR. GRANTLEY W. TAYLOR: Did you find that stretch of 10 cm. of induration?

DR. MALLORY: There was a fairly extensive gastritis on both sides of the tumor, but we did not find any extensive tumor infiltration, in fact it was barely enough to establish the diagnosis.

quadrant, somewhat suggest gallstone colic. At least one attack, however, was thought to be acute appendicitis, because he was brought into the Emergency Ward with that diagnosis. Later he had cramp-like right lower abdominal pain, and then shortly after that, although there is no mention of epigastric pain, the pain came on three or four hours after meals and sometimes was relieved by food and antacids—which suggests gastric or duodenal ulcer. Then it is noted that motion increased the pain. That is a little suggestive of peritoneal irritation, perhaps inflammatory. Next, the pain instead of being intermittent became constant. It started at the right costovertebral angle and radiated around to the right lower quadrant. One might think of some renal lesion. Then the patient thought he noticed a lump 3 or 4 cm in diameter, but this was not confirmed on physical examination despite the fact that he was a thin undernourished man upon whom it was apparently possible to do a satisfactory abdominal examination. The pain again became intermittent and is described as beginning at the right costovertebral angle and radiating to the pubis, suggesting ureteral colic. All this is quite difficult for me to put together. We have two tangible leads—the x-ray study and the gastroscopic examination. I think we might see what the films show.

DR. RICHARD SCHATZKI: A case like this means a lot of worry for the roentgenologist. You can see a large crater, but it is wider and not so deep as that in a case\* we discussed recently. In other words it is not so penetrating in character as the other crater. Furthermore, the surrounding induration is quite extensive, involving an area measuring 10 cm., so that the crater represents only a part of the diseased area. Unless one can demonstrate a definite tumor mass in such a case, I think it is fairly impossible to say from the x-ray whether the lesion is benign or malignant.

DR. WALLACE: At least we have a definite lesion in the stomach. In regard to all the other suggestions,—gall-bladder disease, appendicitis and renal or ureteral stones,—there is very little else in the history or the findings to substantiate any of them. The pyelogram and the Graham tests were negative. The urine is reported as negative. I believe that we can rule out gross disease of that sort.

We come back to the old question, Is the lesion benign or malignant? From the history the type of pain is certainly not that of a gastric neoplasm. There is no mention of epigastric pain. There is a suggestion that the pain came on at a very definite period after meals and that it was re-

lieved by food and soda. The laboratory data add no helpful information until we get to the gastric analysis. That is certainly consistent with ulcer. We are reminded of the statement in the history that "he had had many financial worries," so there is considerable to make us believe that this may have been a benign ulcer.

On the other side of the fence the gastroscopic examination not only revealed the presence of the ulcer, as described by x-ray, but also showed that the ulcer margins and the surrounding mucosa were nodular. That definitely rules out benign ulcer, and so we must assume that we are dealing with a neoplasm of the stomach of some sort. Could this have been a leiomyosarcoma? I judged from reading the x-ray report that there was very little bulk to this tumor, but Dr. Schatzki suggested that there may have been 10 cm of induration.

DR. SCHATZKI: But not a real mass.

DR. WALLACE: That, I believe, is against leiomyosarcoma. It is usually a bulky tumor and less likely to have ulceration of this sort. In the ones I have seen, the outstanding sign has been hemorrhage. We have very little to suggest that in the history, although there were four guaiac-positive stools. The vomitus had not been grossly bloody at any time, and I am inclined to rule out leiomyosarcoma. Some very rare type of sarcoma might explain the picture, but I do not know how one could make such a diagnosis. Certainly it is hard to rule out a carcinoma with central ulceration, though the one thing that makes me hesitate is the high acidity of the gastric contents. One usually expects an acidity in extensive cancer of the stomach. Certainly in a good many cases of cancer of the stomach there is a fairly normal acidity, but I believe it would be very unusual to have as high an acidity as this is.

I am interested in the small, fairly movable, cervical and axillary nodes mentioned in the physical examination. I do not imagine that they were biopsied or there probably would be some note of it. Although Dr. Mallory has, at times, made the statement that in cases of gastrointestinal lymphoma the lymph nodes are likely to show no metastases, I still believe that lymphoma of the stomach might produce this picture. It is more likely to be associated with high acidity than is cancer, and might account for the fullness by rectum, although, of course, that might have been metastatic carcinoma. On the law of averages this ought to be a cancer of the stomach, but I am inclined to make my first choice lymphoma, with carcinoma of the stomach a close second.

DR. EDWARD B. BENEDICT: I did the gastroscopy on this patient, and from the size of the ulcer, the

clinics with the special knowledge that they alone possess. They accept the responsibility of caring for patients after discharge from the clinics and thus relieve the latter of a service they are not equipped to carry. The mutual dependence of these two groups of physicians is evident.

Attempts to organize medical services must recognize those aspects of medicine best designated as its art and its personal relations, as well as its sciences, technics and equipment. The inclusion of all these into the scheme of things is what makes the problem of organization difficult. There seems to be no reason why organization necessitates regimentation, if it be accomplished willingly by those who render the service. There seems no reason to believe that proper organization of medical services should affect deleteriously the position of the family physician. Granted for the sake of argument that specialization is here to stay, the family physician need not be relegated to the bargain basement, but rather elevated to a high position among specialists.

One may well ask whether efficient medical care requires less specialization with more individualistic professional service or more specialization with better co-ordination between the services rendered by specialists, among whom the family physician is the most important.

## CANCER AND CIVILIZATION

ONE of the most frequent misconceptions with regard to the origin of cancer is the belief that it is related to civilization. For years the statement has been current that savage races are practically free from cancer. The reasons for this misconception are obvious. The sick savage rarely comes under formal medical attention, and if he does, the facilities for investigation are such that unless the disease is far advanced or superficial, the chance of diagnosis is relatively slight.

Undoubtedly there are marked variations in the incidence of different types of cancer, but in general the cancer rate tends to maintain a fair degree of constancy in different localities where diagnosis is accurate and medical attention readily

available. In most regions where interest in cancer has been developed, the death rate tends to lie between 110 and 140 per 100,000. We know now that the Chinese have their full share of cancer, with primary cancer of the liver one of the very prominent forms. We know that the natives of India are frequent victims of cancer of the mouth and upper respiratory passages. We know that skin cancer is not infrequent among many of the primitive peoples, particularly in swampy regions where leg ulcers are prevalent and neglected.

One of the most careful recent studies of the incidence of cancer among primitive peoples is that of Bonne and his associates.\* Among most primitive people there is no worth-while evidence as to the incidence of any disease. This is in large part due to the failure of the savage to recognize internal disorders as disease, tending rather to regard them as the effects of the presence of an evil spirit.

If we take the hospital records in Batavia, Singapore or Manila, the liver is the outstanding site of cancer. Virtually none of these cases would be recognized had the patients not died in large hospitals where autopsies are performed. Bonne and his co-workers estimate the incidence of cirrhosis of the liver in the Dutch East Indies as 6.9 per cent for male Malays; this is undoubtedly a factor in the frequency of carcinoma of the liver. In Batavia, among the Malays cancer of the stomach does not appear among the ten commonest forms of cancer although among the Chinese and Japanese its incidence is nearly as high as that in the Western hemisphere. The Malays, however, do show a high incidence of skin cancer and of malignant tumors of the cervical lymph nodes.

When the native population in the Far East is carefully studied, it becomes apparent that, once adjustments are made for age and the high incidence of such infectious diseases as cholera and plague, the incidence of cancer differs but little from that in European or American communities. On the other hand there is material variation in the primary sites of the disease.

## ORGANIZATION OF MEDICAL SERVICES

THE rapid increase in medical knowledge and facilities not only has raised the problem of distribution of costs of medical care but also has created a problem of organizing medical services in the interest of efficiency and economy. In establishing the boards of certification in the various specialties of medicine and surgery the profession has taken cognizance of its being divided into many branches and of the necessity of having qualified specialists. We do not intend to discuss here the pros and cons of specialization. Accepting specialization as it exists today, questions arise which deserve consideration.

One may ask if the profession has taken adequate cognizance of the specialty of "family physician." The question raised differs from one concerned with the importance of the family physi-

cian. The point to be made is whether or not the family physician is trained today purposely to care for the plus or minus eighty per cent of illness for which he is a specialist and gives proper and economical care. And after acquiring his training, is the family physician properly coordinated in the general scheme of modern medicine with other specialties so that there is a reasonably efficient supplementation and a reasonable absence of overlapping? On the one hand, we have the so-called specialists trained in the application of physiological, chemical, pathological or other special knowledge or technics to the diagnosis or treatment of disease. On the other hand, we have the family practitioner who cares for the vast majority of illness that does not demand such technical knowledge but nonetheless calls for a very specialized type of ability. It is as inefficient to have the so-called specialist of today trained to deal with all phases of minor illness, which he never sees, as to have the family practitioner trained to use technical knowledge and facilities for which he will but occasionally encounter the need.

A sound approach to an economical and efficient organization of medical service is based perhaps on a recognition of the truth of two statements in which a paradox seems to appear but actually does not occur. First, medical knowledge and art have grown beyond the capacity of the individual physician. Secondly, eighty per cent of society's ills can be properly cared for by the family physician.

Under a properly organized medical service there is no antagonism between the specialists of the large clinics and the family practitioners. The services of the one supplement those of the other in a field so vast that neither alone is adequate. The former make available to the practitioner diagnostic special treatment clinics. They introduce new methods of medical and surgical therapy. They give teaching clinics, publish papers and speak before medical societies, and thus, free of charge, give to the practitioner the new medical knowledge that from year to year becomes his stock in trade. On the other hand, the practitioners refer patients to the clinics. Many of them give much of their time and experience to the clinics, thus providing the

lacerated The fundus was examined manually and found not to contain any placental tissue The uterus was packed in consequence, and the patient was transfused Years ago hot intrauterine douches were frequently employed in cases of this type, they are rarely resorted to now

#### MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning February 13

##### BRISTOL NORTH

Thursday, February 16, at 4 00 p m., at the Morton Hospital, Taunton. Subject—Bright's Disease and Hypertension Evaluation of new therapy Diagnosis. Instructor W Richard Ohler Lester E. Butler, *Chairman*

Tuesday, February 14, at 4 00 p m., at the Union Hospital, Fall River Subject—Syphilis Latent syphilis—diagnosis and treatment. Instructor Francis M. Thurmon. Howard P Sawyer, *Chairman*

##### MIDDLESEX EAST

Tuesday, February 14, at 4 00 p m., at the Melrose Hospital (Colby Hall), Melrose. Subject—Whooping Cough The present status of vaccine therapy both as prophylactic and therapeutic measure, the early diagnosis by laboratory procedures, and the treatment of complications Instructor R. Cannon Eley Walter H. Flanders, *Chairman*

##### MIDDLESEX NORTH

Thursday, February 16, at 4.30 p m., at St. John's Hospital, Lowell Subject—Gonorrhea Modern treatment of gonorrhea. Instructor Weston T Buddington. William S Lawler, *Chairman*

#### REGULATION OF THE PRACTICE OF MEDICINE IN MASSACHUSETTS\*

There are in Massachusetts, as in every other state, several kinds of regulation of the practice of medicine, but the only kind that I shall talk about today is control by law This regulation may be described in a general way by saying that the State declares that certain persons shall be licensed to practice medicine and it prohibits the practice by any unlicensed person.

This does not mean that the State sets forth in detail how a doctor shall treat his patients If he is licensed he may use drugs or he may operate, he may treat the mind or treat the body by means of massage or exercise, he may employ any resource of any of the cults, according to his own judgment and conscience. But his practice may be stopped if he becomes insane or a felon or a drug addict, or if he is guilty of deceit or of gross professional misconduct,—whatever that may be,—or if he violates any law of the Commonwealth with ref-

erence to the practice of medicine. It is of supreme importance that only the right kind of person be admitted to practice. I shall point out to you later that in spite of its importance, the kind of person is one of the things to which the statute pays little attention.

Ordinarily if one is planning a course of action, such as, for example, the regulation of the practice of medicine, one attempts to make clear just what it is that one is trying to regulate. The physician wants to know in a general way what he may do, the patient wants to know what may be done to him, and the court may want the guidance of a law when it has to decide whether a given act is or is not illegal

Massachusetts has never attempted to define the practice of medicine, although in nearly every other state of the Union there is some definition, generally regarded as very satisfactory for the purposes of administration. Two objections have been raised here, first, it cannot be done—if you try you will put in something you do not want, and you will leave out something that ought to go in, secondly, it is not necessary—we have always gotten along without it. These objections may be real or imaginary

It would be interesting to review historically, if there were time, the changes which have taken place in what is meant by the practice of medicine, especially since there is still confusion in the minds of many persons. The word medicine has today at least three meanings, which give no trouble in ordinary conversation but which have caused much discussion when the enforcement of the law is under consideration.

When we say medicine we may mean a drug as distinguished from a food, or we may mean a branch of the healing art which is distinguished from surgery, or we may mean the whole healing art itself as distinguished from law or theology or engineering There are always those who say they are not practicing medicine because they do not use drugs or because they do not operate. Yet they are practicing medicine because they are treating people who are sick for the purpose of giving relief (perhaps even of making them well), and it would be helpful in law enforcement if the statute said just this

Why should the State forbid the practice of medicine by any person who is not licensed? Many persons have asked this question, and there are at least three groups in the community who as a matter of principle deny the right of the State to interfere with the practice of medicine. But it is not worthwhile to discuss these views now, however important they may seem to the holders thereof, as the courts have on numerous occasions upheld the power of the State to determine the conditions under which medicine may be practiced. At one time there was no statutory regulation in Massachusetts. Then came a period of regulation, closed in 1859 by the abolishment of all state control, for reasons which we cannot go into now. It is interesting to note that Massachusetts was the last to take this backward step For thirty five years only the criminal law was effective. Then in 1894 Massachusetts again decided that some regulation was necessary and created a Board of Registration in Medicine. It was next to the last state to do so Of the striking slowness of Massachusetts to enact legislation to protect its citizens against unqualified practitioners of medicine, I shall speak again later

The reason why such protection is necessary is that most people have no way of telling by their own judgment who is a competent physician, nor can they tell very well even by experience. It is a field outside of anything of which they have adequate knowledge. Through im-

## POSTPARTUM HEMORRHAGE

Mrs. M. B., a twenty-one-year-old primipara at term was admitted to the hospital in labor on November 10, 1938.

Her family history contained nothing of unusual note. The patient had had measles and scarlet fever. Catamenia began at twelve, were regular, with a twenty-eight-day cycle, and lasted four days. Her last period was February 1, making her expected date of confinement November 8. The pregnancy had been uneventful.

Physical examination on entry showed a well-developed and nourished young woman. The heart was not enlarged, there were no murmurs. The lungs were clear and resonant, there were no rales. The fundus was 30 cm. above the symphysis. The vertex presented in the ODP position and was lightly engaged. The fetal heart was distinctly heard in the right lower quadrant. On rectal examination, the cervix was found to be soft and partly taken up. The os admitted one finger, and through this the presenting part could be felt in high mid-position. The sacral promontory did not protrude abnormally, the vaults were free, and the pelvic outlet was ample. The membranes were intact. There was no edema of the extremities. The temperature, pulse, respirations, blood pressure and urine were all normal.

The patient had an inactive labor, her pains coming at irregular intervals and being of varying intensity. Nembutal, in moderate dosage, was used for the control of pain. At the end of about thirty hours she was fully dilated, with the occiput rotated to a right transverse position. The contractions at this time were good, but still irregular. Gas and oxygen was given with the pains for about an hour, with the patient bearing down during contractions, but little was accomplished either in rotation or descent of the head. Because of this lack in progress forceps delivery was decided on. Under nitrous oxide, oxygen and ether anesthesia a forceps was applied to a partially rotated ODP, after a right oblique episiotomy, and delivery of an 8-pound, 10-ounce baby

was effected without undue traction. The episiotomy was sutured in routine fashion.

Fifteen minutes after the birth of the baby, the placenta separated and was expressed from the lower uterine segment by moderate pressure on the fundus. An ampule of Ergotrate was injected into the thigh muscles at this time. The placenta and membranes were found to be complete. The fundus did not contract well, and a large quantity of blood was expelled from the vagina. Pituitary extract and more ergot were given intramuscularly, ice was applied to the fundus and it was held lightly. As more than normal bleeding continued though the fundus seemed firmer, the cervix was examined digitally. No deep tear was felt on either side. The foot of the bed was tipped up, ice was continued on the fundus, and glucose in saline was started intravenously. At this time the patient was pale, with a pulse of 120, her blood pressure, despite the blood loss, was 120 systolic. Typing for transfusion was begun. The uterine muscle remained flabby, and while no large hemorrhage occurred, there was a steady staining of the vaginal pads which was considerably more than normal in amount. One-quarter grain of morphine was given subcutaneously.

Three hours after delivery, with the hemorrhage continuing, the pulse 130 and the blood pressure 100 systolic, the uterine cavity was explored manually under nitrous oxide and oxygen anesthesia. No remnant of placenta could be felt, and with a speculum in the vagina, no marked cervical tear was found. The uterus and vagina were firmly packed with gauze and an ampule of Ergotrate was injected intravenously. The patient was then transfused with 500 cc. of citrated blood. Her condition improved rapidly. She did not stain through the packing, the fundus remained firm around the gauze, the pulse came down to 100, the blood pressure went up to 120 systolic, and her color improved. At the end of twenty hours the packing was removed from the vagina and uterus. No hemorrhage followed. Fluids were forced and iron given by mouth thereafter, and the subsequent puerperium was uncomplicated.

*Comment.* This case of uterine atony is typical of those patients who have no profound hemorrhage but continue to bleed without showing normal periods of contraction. No great amount of blood was lost at any time, and yet the blood pressure continued to fall and the pulse became more rapid—not over a period of minutes but during the course of two or three hours.

The usual treatment of cases that continue to bleed as this one did was carried out successfully. The cervix was inspected and found not to be

other states have gone ahead, Massachusetts has stood still. It is true that in 1936 a law was passed giving power of approval of medical schools from which candidates are admitted to examination, which law, if effective, would put Massachusetts approximately on the level of most of the other states, but the effective date of the act, set originally for January 1, 1939, was changed by the legislature this year to January 1, 1941.

Q Why was this postponement authorized?

A. There was very powerful opposition to the bill before it became law, and since then there have been very vigorous efforts to make the law of no effect. If you are really interested in this question, I suggest that you should interest your own senator and your own representative in the General Court. I can assure you that opposition to this law is not offered by those that have the health of the public—that is to say, your health—as their first interest.

## MISCELLANY

### CONNECTICUT NEWS

#### HURRICANE AND FLOOD

On September 21, and for several days following, Connecticut suffered a major disaster with irreparable loss of life and property. A tidal wave wiped out many summer colonies. The maximum water level for the Connecticut River at Hartford was 35.4 feet above mean sea level, only about 2.2 feet below the record 1936 flood level. Public water supply systems and sewage-disposal systems were damaged, many sections were flooded by polluted water, wells were contaminated, and relief workers were exposed to possible outbreaks of intestinal disease. In spite of all this, very little illness resulted. To the state and local health departments and to the Red Cross is due much praise for excellent preventive health work. Sixty-eight deaths resulted from the hurricane, 56 of these from drowning and 12 from collapse of buildings or from falling trees.

#### MIDWIFE INSTITUTE

The Fifteenth Annual Midwife Institute was held at the New Haven Department of Health on November 3. The institute affords the midwives in the State an opportunity to learn new methods for caring for maternity patients and newborn infants. In addition to 22 midwives, several health officials, public health nurses and hospital maternity nurses attended.

#### NEW CHIEF OF DIVISION OF CRIPPLED CHILDREN

Following the resignation of Dr. Russell V. Fuldner as chief of the Division of Crippled Children, Connecticut Department of Health, the appointment has been announced of Dr. Louis Spektor as his successor. Dr. Spektor is a graduate of Trinity College and the University of Rochester School of Medicine. He served an internship at Duke University Hospital and has specialized in pediatrics.

#### REPORT OF STATE HEALTH COMMISSIONER

Dr. Stanley H. Osborn, state health commissioner, in his biennial report to Governor Cross, made the following recommendations: (1) the appointment of a properly trained and qualified person to advise on housing activities and slum-clearance programs, (2) the furnishing of suitable quarters to house the Connecticut Department of Health, (3) the establishing of state grants to towns to aid them in forming co-operative full time health depart-

ments under the Sanitary District Law, (4) the appropriation of a contingent fund that will be available to handle the emergencies affecting the health of the State between sessions of the General Assembly, (5) the instituting of an intensive case finding program to aid in locating early cases of tuberculosis in the small cities and towns, (6) the beginning of a pneumonia program for supplying service for pneumococcus typing and for purchasing anti-pneumococcus serums to be used by those unable to pay for them, (7) the allotment of an appropriation to assist towns to carry out indexing and binding of their old vital-statistics records, started by the State in 1935. The Public Health Council whose report accompanied that of the commissioner recommended: (1) an increase in the budget of the Connecticut Department of Health from \$850,000 for two years to about \$1,400,000 and (2) financial state aid to towns lacking adequate tax receipts so that sufficient state and local money may be available to match federal funds for health projects. Connecticut's death rate of 10.1 deaths per 1000 population in 1937 was equal to the lowest in the history of the State and was lower than that of Massachusetts, Rhode Island or New York.

#### PREPAYMENT HOSPITALIZATION UNDER STATE CONTROL

A bill setting up regulations for the operation of non-profit corporations providing hospital-care insurance on a prepayment basis has been approved by the Governor's Committee on Prepayment Hospitalization. This bill will be introduced at the coming session of the General Assembly. The bill, placing supervision of all such plans in the hands of the insurance commissioner, would permit the continuance and expansion of the three plans now operating in the state, the organization of new plans where needed and the merger of any or all of them. The Governor expressed his appreciation of the work of this committee. The report of the committee, which is headed by Dr. Wilmar M. Allen, director of the Hartford Hospital, made twenty specific recommendations.

#### PREPAYMENT HOSPITALIZATION SPREADS TO HARTFORD

The Plan for Hospital Care, Incorporated, a non profit organization designed to cover future hospital bills of every employed man and woman, is now in operation in the Hartford area. Already in successful operation in New Haven and Waterbury and having a state membership of more than 44,000 persons, it has now added to its list of member hospitals the following: Hartford Hospital, St. Francis Hospital (Hartford), Mt. Sinai Hospital (Hartford), Manchester Memorial Hospital, Charlotte Hungerford Hospital (Torrington), and Middlesex Hospital (Middletown). The Plan for Hospital Care was inaugurated in Connecticut in September, 1936, the first subscribers joined in April, 1937, and within eighteen months the plan became the twelfth largest of the forty similar plans throughout the United States.

#### HARTFORD INFANT MORTALITY RATE

Hartford's infant mortality rate for 1937 was 32.25, a much lower rate than that for the United States as a whole. Premature birth and injuries at birth are two factors of importance in maintaining the infant mortality rate as high as it is.

#### WHOOPIING COUGH

Whooping cough ranks first in Hartford as a cause of death among the communicable diseases of childhood. The average number of deaths per year during the last

memorial tradition and custom and through actual knowledge and skill, the physician possesses vast power. In the nature of the relation of physician and patient, this power must often be exercised with no control except the conscience of the physician. For example, at the time of an emergency there can be no outside control. It is on account of this vast power and the danger from its improper use that the public should be protected against unqualified physicians, whether they be ignorant or unskillful, but especially if they be not conscientious and do not safeguard the welfare of the patient.

How is the regulation of the practice of medicine carried on in Massachusetts? Since 1894, as previously stated, there has been a Board of Registration in Medicine, consisting of seven physicians who have been at least ten years in practice, appointed by the governor (one each year), with the approval of the executive council. The choice of the governor is subject to two important restrictions: no member of the Board can be a teacher in a medical school, and not more than three members of the Board can be members of one chartered state medical society. The second restriction was perhaps of some value when there were three state medical societies and when the spirit of partisanship ran high. It is of doubtful value at the present time. The first restriction, preventing teachers of medicine from being appointed to the Board, was presumably to prevent them from using undue influence in assisting the graduates of medical schools in which the men were teaching. This restriction also is of very doubtful value at the present time, and it has a clear disadvantage because it gives preference to examiners who are least likely to know how to give examinations and how to judge the results. This is important because other provisions of the statute make ability to pass the examination the chief test of fitness to practice medicine.

The Board then, acting under special directions of the statute, has two chief duties: to license physicians whom it deems qualified, and to unlicense physicians, once deemed qualified, who by their action have shown cause for disqualification.

The conditions for admission to examination for license are that the candidate must be twenty-one years of age, of good moral character and a high school graduate and, after attending a four year medical course of not less than thirty-two weeks in each year, must have received the degree of doctor of medicine or its equivalent from a school legally chartered and empowered to confer such a degree. Concerning the examination the statute says it shall include certain subjects but makes this significant requirement: It shall be sufficiently thorough to test the fitness of the candidate to practice medicine.

This raises at once the question whether any examination that the Board can give will fulfill this condition. The fundamental tests of fitness are knowledge of the body and the mind of the patient, knowledge of the resources of the science and the art of medicine, skill in their application, sympathetic understanding of humanity, and a character which will enable the physician to carry well the responsibilities of his profession.

A written examination can be devised to test knowledge, a practical examination will test skill. But what examination can the Board devise for finding out the kind of person the candidate really is? The statute shows too much confidence in the adequacy of examinations. This confidence is not justified by the results. In this respect Massachusetts differs again from the statutes of nearly all the other states. If the candidate meets the requirements of the statute and passes the examination, he is given a license to practice.

Taking away the licenses of physicians deserves much more time than can be given to its consideration now. I have already referred to some of the disqualifications because of which a license may be suspended or revoked, and most of these need no further comment because they are clear and definite. But one may well ask the meaning of "gross misconduct in the practice of his profession," which is one of the reasons given for taking away a physician's license to practice. Objection has been made by certain persons to the use of such a vague expression, although a similar phrase occurs in the statutes of other states. But the courts have upheld the use of the words "gross misconduct." The significance of the phrase lies in the suggestion that there is a relation between physician and patient (different from a business contract) which is fundamental. There is usually no formal contract between the physician and the patient. But when the patient places himself in the care of the physician, he entrusts his well-being to the doctor, and the two persons, without any formal contract, might be said to be like a trustee of a trust fund and the beneficiary of the trust. Any failure on the part of the physician to discharge faithfully the duty of physician as trustee may be regarded as professional misconduct.

Q Does everyone who wishes to practice medicine in Massachusetts have to pass the examination set by the Massachusetts Board of Registration in Medicine?

A The law says he must pass a written examination but it also specifies one examination which the Board may accept in place of its own. This is the examination set by the National Board of Medical Examiners.

Q Is this National Board part of the federal government?

A No, it is a private organization which includes representatives of the medical branches of the federal government as well as representatives of several private medical organizations of national scope.

Q Does the license of the National Board permit practice anywhere and everywhere in the United States?

A No, the National Board has no power at all to license, and the certificate which it gives is called a diploma, certifying only that the candidate has passed the examination.

Q How many states are authorized by their laws to accept the National Board examination?

A There are now over forty states which accept this examination in place of their own.

Q Why do so many states accept this examination if it is given by a private organization?

A The requirements for admission to this examination have been so high and the examination has proved to be so searching and so comprehensive that it has come to be regarded as more difficult than any state board examination.

Q Does any state accept the examination of another state in place of its own?

A Yes many states issue licenses on the basis of what is called reciprocity between the states. But it is interesting to note that no other state has established reciprocity relations with Massachusetts in this respect.

Q Why is that?

A That is because for years the standards for admission to practice medicine in Massachusetts have been so low that no other state would accept them.

Q But you do not mean to say that Massachusetts is below the other states in its standards?

A Yes. That is just what I mean to say. While the

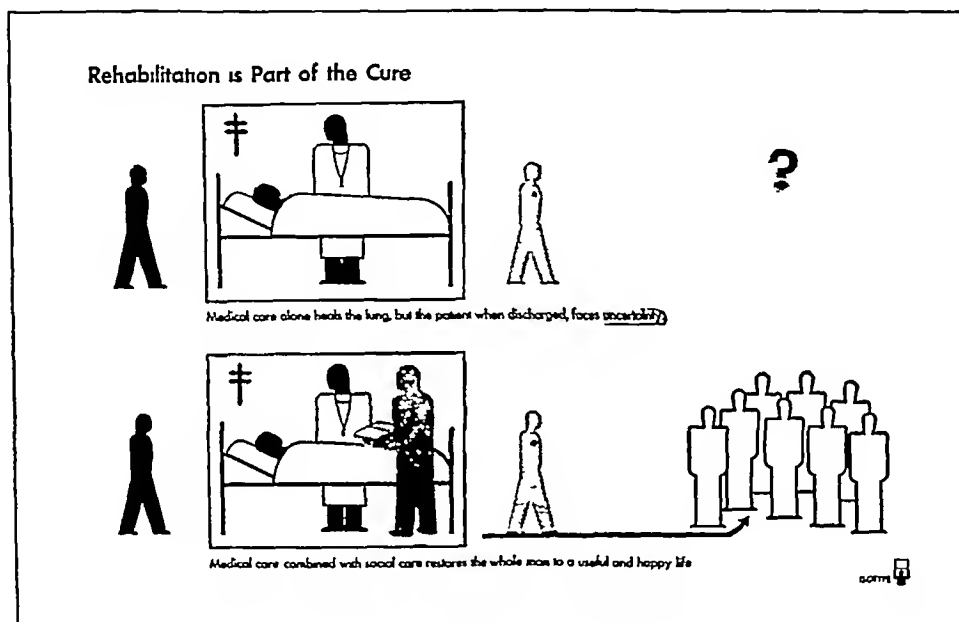

ments represent only a small fraction of the large number of handicapped persons and that resources are limited. The remedy for this lies in broadening the scope of rehabilitation service through legislation.

The California Bureau of Vocational Rehabilitation has at this time a live roll of 659 tuberculous patients and ex-patients. Each year since 1933 has seen an increase in the number enrolled. During this time 758 persons (31 per cent) out of a total of 2418 in training have been rehabilitated, which means, placed in a suitable job with a fair salary, and each year the proportion of those rehabilitated has increased.

How permanent is the rehabilitation of ex-patients? Of 209 individuals rehabilitated in Los Angeles County during the period of 1928 to 1936, 155 (74 per cent) are still employed, whereas in a control group of 98 individ-

proximately 8 per cent of our tuberculous patients start their training before discharge, either in one of the five sanatorium commercial classes conducted by the Bureau, or by means of correspondence courses, or through employment training in sanatorium jobs. The advantages of this early start are improved morale, service as a hardening process, shortening of period of continued training after discharge and often either immediate or at least quicker placement. Training is always in accordance with medical advice, starting with a few minutes daily and increasing as the patient's condition permits.

Training is usually provided after discharge and after a period of adjustment to home conditions. The start is on a part-time basis, increasing to full time as condition warrants, and provision is always made for medical follow up. Each training program is made to fit the par-

*This is Number 14 of a series of twenty isotype charts on tuberculosis. The original charts are in color each measuring 24 by 36 inches and are used by tuberculosis associations for the education of the general public.*

uals discharged from sanatoriums who had not received training the number still employed is 34 (34 per cent). Not so favorable was the discovery that about 20 per cent of the rehabilitated individuals had had relapses of their disease and 4 per cent died, though the work was not the cause of death.

Experienced counselors of the Vocational Rehabilitation Service make periodical visits to sanatoriums throughout the State. They counsel patients who have been selected by the medical director and who are deemed eligible and feasible with regard to future occupation. Occasionally, preliminary guidance interviews are given to patients not yet ready for decision but who need reassurance.

Vocational training is seldom a part of the sanatorium program. We believe that selected reading activities, adult education and occupational therapy fit better into the sanatorium situation, with as much prevocational emphasis as may be desirable in individual cases. Nevertheless training is occasionally provided for selected patients whose condition is at least quiescent and improving to indicate discharge within a reasonable time, and assuming that training facilities are or can be made available. Ap-

ticular needs, interests, and convenience of the individual trainee to the greatest extent possible, never do we try to fit the trainee into a cut-and-dried uniform program. Under these conditions we find that training may be successfully followed, this results in successful rehabilitations.—Reprinted from *Tuberculosis Abstracts*, January, 1939

## CORRESPONDENCE

### THE DOCTORS' GREEN CROSS

*To the Editor* The green cross on the white field, which designates a doctor's automobile and which originated in Boston, is now in general use all over the country. I have been urged to record, from personal recollections of the circumstances, the story of its origin.

The device was first suggested by the late Dr. Samuel Crowell, who up to the time of his death lived and practiced in the Dorchester district of Boston.

In the early days of the automobile, a small group of the members of the Norfolk District Medical Society, including Dr. Crowell, and Dr. Arthur Perry and Dr. Joseph

ten years for whooping cough has been 4.4, for measles 3.7, for diphtheria 2.3 and for scarlet fever 1.4. All deaths from whooping cough have been among children under four.

#### EXPANSION OF MT SINAI HOSPITAL

A \$250,000 program for building improvements and expansion of Mt. Sinai Hospital, Hartford, has been announced. A campaign for funds will be formally launched in February. The present structure will be renovated and an east wing added, thus increasing the hospital bed capacity to more than 100. Clinical facilities will be enlarged and additional private rooms will be provided. The outpatient department will be expanded. The new wing, to be constructed of red brick with brownstone trim, will be three stories high and will provide about 22,000 additional square feet of space.

#### DEBATE ON SOCIALIZED MEDICINE

The Get Together Club of Hartford recently held a debate on the subject of socialized medicine at one of its regular monthly meetings. Dr. Creighton Barker, of New Haven, executive secretary of the Connecticut State Medical Society, presented the platform of organized medicine, while Dr. Kingsley Roberts, of New York, medical director of the Bureau of Co-operative Medicine, advocated health insurance under the co-operative plan. Disagreement between the two speakers centered around the point that salaried physicians would be inferior to fee paid physicians where the former are grouped together and paid fixed salaries through a third party.

#### DR NOVAK GUEST SPEAKER

Dr. Emil Novak, of Baltimore, was selected to be the guest speaker at the first public meeting sponsored by the Medical Information Bureau of the Hartford Medical Society and the Hartford County Medical Association. His subject was Cancer: A message of hope. About 2500 people from Hartford and the surrounding towns were present to hear Dr. Novak's very timely and interesting lecture.

#### LECTURE SERIES AT NEUROPSYCHIATRIC INSTITUTE

On November 2 the first of a series of staff lectures was held at the Neuropsychiatric Institute of the Hartford Retreat. The speaker was Dr. Lawrence Kolb, assistant surgeon general of the United States Public Health Service, and his subject 'Drug Addiction'. Dr. Kolb expressed the belief that due to the Harrison Narcotic Act of 1915, drug addiction is not increasing in the United States at present, except perhaps in the case of marijuana. On November 16 Dr. Bernard Dattner, of Vienna, spoke on Syphilis of the Nervous System. He outlined the methods used in fever therapy for cerebrospinal syphilis.

#### HARTFORD HOSPITAL STAFF APPOINTMENTS

The Board of Managing Directors of the Hartford Hospital at its annual meeting recently announced the appointment of the hospital staff for the ensuing year. Twenty-one promotions and four new members were announced. The new appointments, all as clinical assistants, follow: Dr. Frank O. Wood, Department of Obstetrics and Gynecology; Dr. Wendell C. Hall, Department of Radiology; Dr. William J. Neidinger, Department of Otorhinolaryngology; Dr. F. Earle Kunkel, Department of Dermatology.

#### APPOINTMENT OF NEW MEDICAL EXAMINER IN HARTFORD

Dr. Perry T. Hough was appointed medical examiner in Hartford in October to succeed Dr. Henry N. Costello. Dr. Hough is a graduate of Trinity College and McGill University Faculty of Medicine and served an internship at the Hartford Hospital. At present, Dr. Hough is assistant pathologist of the Hartford Hospital and pathologist of the Municipal Hospital, Hartford, and of the Manchester Memorial Hospital.

#### HEALTH OFFICERS APPOINTED

The following new appointments have been announced: Walter S. Lay, M.D., as health officer of Hamden; Josephine Evarts, M.D., as health officer of Kent; Reuben Rothblatt, M.D., as acting health officer of Willimantic; Samuel S. Fargo, M.D., as health officer of Pawcatuck; and Helen Baldwin, M.D., as health officer of Canterbury.

#### CONNECTICUT DEPARTMENT OF HEALTH PERSONNEL APPOINTMENTS

Ralph F. Sikes, M.D., has been appointed to the Bureau of Preventable Diseases during the absence of Charles E. McPartland, M.D., for advanced study in public health. B. Arthur Moxness, M.D., has been appointed under the merit system to the Bureau of Venereal Diseases as public health physician.

#### COUNSELING THE TUBERCULOSIS PATIENT

What becomes of the tuberculous patient after the doctor refers him to the sanatorium? In many communities sanatorium officials send progress reports to the practicing physician from time to time. Sometimes, however, the doctor is revisited by the patient whom he sent to the sanatorium months or years before, asking advice as to his future course. He may wish particular advice on the kind of work he may do safely. It may be helpful, therefore, to learn from a qualified official what provisions are made by the state for counseling and training tuberculous patients for suitable employment. Extracts of a paper (Counseling and training tuberculous patients for suitable employment. *Tr. Nat. Tuberc. A.*, 1938) by H. D. Hicker, chief of the Bureau of Vocational Rehabilitation of California, follow.

Not only medical skill is necessary to restore the tuberculous patient to a useful life, but also the aid of mental hygiene, social welfare, education, training and placement services. Each patient must be treated as an individual, yet one must remember that the individual is not an assembly of parts and functions and that, therefore, he must be treated as a whole. Consequently all workers in the field of tuberculosis must co-ordinate their services. Vocational rehabilitation is closely linked with medical and social services.

Under the Federal Rehabilitation Act of 1920 and the subsequent state rehabilitation acts, tens of thousands of men and women with physical disabilities of various types have achieved satisfactory vocational adjustment. It has been amply demonstrated that the rehabilitation program of vocational counseling, training and other related services can and does make physically impaired persons employable. Yet comparatively few tuberculous patients have received the benefits of the rehabilitation service. Among the reasons given for this lack are that the rehabilitation service has shared the widespread fear of this disease and the belief that very few cases recover sufficiently to be come employable. Another reason is that tuberculous pa-

matrix goes into solution. Hence, if we decalcify a stone, there is no longer any stone. This type of stone is not formed unless the urine is of such a composition as to cause precipitation of the crystalloid. Calcium phosphate and calcium carbonate stones are formed in an alkaline medium. A calcium oxalate stone will form in either acid or alkaline urine, and uric acid and cysteine stones are formed in acid urine.

*In vivo*, two possibilities of controlling stone formation present themselves. We can alter the composition of the diet and restrict the fluid, or we may be able to inject some dissolving fluid into the renal pelvis which will not harm the patient.

Since calcium carbonate is the commonest constituent of stones, we used this as a test substance. At pH 6.5 the solubility product of calcium carbonate is such that most of the ions precipitate out. At pH 4.0 the solubility product changes so that there is a greater tendency for the precipitated salt to dissolve, but an equilibrium is established which prevents its complete solution. If, to such a system, citrate ions are added, they form a complex soluble salt with the calcium ions, and the reaction can go in only one direction, namely to complete solution of the salt. At 40°C. the reaction progresses three times as fast as at room temperature.

*In vitro*, we have used an isotonic sodium citrate and citric acid solution at pH 4.0 in a constant exchange apparatus and have seen moderate sized stone completely dissolved in twelve to nineteen hours. Calcium oxalate stones, of course, are not affected.

These preliminary experiments suggest that the *in vivo* dissolving of stones is a possibility.

#### PRESACRAL NEURECTOMY FOR DYSMENORRHEA Dr. Joe V. Meigs

The treatment of dysmenorrhea is frequently unsatisfactory and limited to the use of antispasmodics, such as belladonna. In 1924 Koch performed the first presacral neurectomy and the operation has since met with considerable success—but always in combination with cervical dilatation, uterine suspension or some form of plastic operation. We have undertaken to use presacral neurectomy alone, and the first of 20 such cases has now gone seven years since operation.

The superior hypogastric plexus is essentially autonomic, containing fibers which mediate vasomotor control sphincter control and muscle tone. In addition it contains sensory fibers, for we have long known that crushing the plexus causes pain in the bladder. Endometrial biopsies also cause pain. Following operation we have found no pain on uterine scraping, though the backache of cervical dilatation persists.

While not especially difficult technically, the operation is tedious and time consuming, for the entire area between the bifurcation of the aorta and the bifurcation of both iliac arteries must be completely denuded of nerve fibers. Fibers which commonly pass beneath the aorta and those branches coming from the inferior mesenteric artery must not be overlooked.

Seventy-five per cent of the operations have been completely and 10 per cent partially successful. The 3 unsuccessful cases included one patient with a small right cervix, one who continued to complain of pain in order to get operative sterilization and one in whom some fibers were apparently not cut. Three of the patients have subsequently borne children. One had less pain than with previous deliveries, one had no cramps but only a rhythmic backache during labor and one seemed to have the usual amount of labor pain. Several of the patients

previously complaining of dyspareunia have reported no such trouble since operation.

Hence we believe that presacral neurectomy by itself is satisfactory therapy in cases of the essentially uterine types of dysmenorrhea.

#### CARCINOMA OF THE LIP Dr. Grantley Taylor

The problem of treatment of primary cancer of the lip is fairly well settled as being a matter of adequate surgical excision and irradiation. The question of what to do in the neck is still controversial, however. For this reason 600 cases of cancer of the lip at the Huntington Memorial and Pondville hospitals were studied to find out what characteristics of the primary lesion would affect the presence or absence of lymph node metastases. The conclusions were as follows.

- (1) The larger the primary lesion the more likely is the presence of cervical node metastases.
- (2) Though somewhat less dependable due to poor histories, the longer the duration of the primary lesion the more likely the metastases.
- (3) The more malignant the growth the more likely the metastases. (Slides from the primary lesions were all examined by Drs. Benjamin Castleman and Shields Warren.) This ranged from 6 per cent metastases for Grade I lesions to 32 per cent metastases for Grade III lesions. Fortunately, cancer of the lip is usually a low grade tumor.
- (4) Recurrence of the primary lesion is more likely to be associated with metastases.
- (5) The larger the palpable lymph nodes the more likely the presence of metastases. This ranged from 8 per cent with non palpable nodes to 91 per cent with 2-cm. nodes. Frequently, however, large lymph nodes are only inflammatory.

Thus we can make no laws about dissection of the neck in cancer of the lip. It is probably best to wait and see and thus avoid unnecessary surgery—but not to wait until the possibility of cure is unlikely. Sixty-four per cent of the nodes were positive when neck dissection was delayed, so that there seems to be less likelihood of cure if we wait for clinical nodes to appear. If the patient is dependable and can be closely followed and if the primary lesion is small, waiting is wise. If undependable, neck dissection must be resorted to immediately.

#### ADRENAL CORTICAL TUMORS Dr. Oliver Cope

We now recognize three syndromes of adrenal cortical hypersecretion: virilism in the female, the basophilism syndrome described by Cushing, and feminization in the male.

Diagnosis is difficult in the early stages for there are no fool proof signs. Even androgen assays of the urine are equivocal in borderline cases. Enlargement of the adrenal gland is the most important sign but it is not palpable and cannot be seen on x-ray films until it is quite large and distorts or shifts the renal shadow.

For this reason, with the co-operation of Drs. E. D. Churchill and Richard Schatzki, we have studied 56 cases using the perirenal air insufflation technic. In 15 cases the adrenal was seen at operation and in 1 at postmortem, so that the apparent size on the film and the actual size could be compared. In all cases pyelograms gave no information. Both sides were always examined. Tumors when present were always visualized. Exclusion of tumor when suspected saved many exploratory laparotomies. A check on the size of the non tumorous gland before removal of

Stedman, both of Jamaica Plain, with a few others, all of whom are now dead, waited upon the Board of Street Commissioners of that day, asking for some sort of preferential consideration for doctors' cars on the road. As a result of this conference, the commissioners agreed to allow doctors whose cars should bear a distinguishing device to park left wheel to the curb in certain suburban areas while making professional calls.

The question then arose as to what distinguishing device should be adopted. A red cross seemed to be the favorite, but Dr. Crowell pointed out that the red cross belonged to the Red Cross and not to the medical profession. He suggested that since green had been the color of the Medical Corps of the Union Army during the Civil War—green sash for commissioned officers and green stripes on breeches for enlisted personnel—that a green cross on a white field would be appropriate. This seemed to be acceptable to all, and on December 10, 1908, the Board of Street Commissioners adopted and promulgated a regulation embodying the above provisions.

Twenty years later, on September 21, 1928, when the Boston traffic regulations were revised, that regulation which had given to doctors' cars a special parking privilege was rescinded. Today, while the green cross has no official status, at least in Boston where it had its birth, it is still widely honored by traffic officers, who for the most part are very considerate of the traffic problems of the doctor.

Boston

## REPORTS OF MEETINGS

### SUFFOLK DISTRICT MEDICAL SOCIETY

The Suffolk District Medical Society met at the Boston Medical Library on Wednesday, November 30, 1938, under the chairmanship of Dr. Reginald Fitz. The program consisted of a presentation of recent work done at the Massachusetts General Hospital.

#### PULMONARY EMBOLI: PATHOLOGICAL ASPECTS Dr. Benjamin Castleman

Careful correlations between x-ray findings and postmortem findings are usually impossible because of the pathologic changes that occur between the taking of good x-rays and death, the unsatisfactory quality of antemortem films which of necessity must be portable, and the collapsed state of the lungs post mortem.

To circumvent these difficulties we are now taking anteroposterior and lateral postmortem 7-foot chest plates with the patient upright. At postmortem the lungs and trachea are removed together, formalin is then poured into the trachea until the lungs are distended to normal size, when the trachea is tied off. The entire preparation is then put in formalin and a week later the lungs are sectioned and an attempt made to account for every shadow on the films. Lungs from 400 cases have been examined.

In 3500 routine autopsies, 9 per cent showed emboli or infarction of the lung, and in 3.5 per cent the embolus was the cause of death. In this series of 400 autopsies, 14 per cent showed emboli or infarction, an increase of 50 per cent. Molds were made of the shape of each one, and none showed the traditional triangular shape. Frequently the costophrenic angle infarcts showed a convexity toward the hilum. All infarcts were peripheral, that is,

on a pleural surface of the lung, and they can occur wherever two surfaces of pleura meet.

From this work and simultaneous experimental work, we now have a fairly clear picture of what transpires when an embolus reaches the lung. The first day the infarcted lung still contains a good deal of air in the alveoli and there is no sharp line of demarcation between infarcted and normal lung, nor is there any destruction of alveolar walls. By the third day there are still some air-containing alveoli, but a sharp line of demarcation is present and red-blood cells and white-blood cells are found in the alveoli and in the walls. Still later, the infarcted area becomes encapsulated and there is almost complete necrosis of the alveolar walls. Complete healing is evidenced by an organized fibrous scar—which shows as a linear shadow on the x-ray film.

This complete progressive picture, however, is only seen in a lung previously damaged, as in chronic congestion, and this we call a true infarct. If the lung is essentially normal, the process only goes as far as edema and hemorrhage into the alveoli, which still contain some air, it then resolves without ever developing necrosis of the alveolar walls. This we speak of as incomplete infarction. In such cases the x-ray film shows only a transient shadow, which is not very dense and is in keeping with the pathologic picture.

Postoperative and postpartum patients frequently have signs and symptoms of pulmonary infarction, show a vague shadow on x-ray for just a few days and never develop signs of fluid. These patients do not die, so we never see the lesions. If these were true infarcts,—that is, had alveolar wall necrosis,—they would heal by organization and last longer according to x-ray. Hence, they are probably cases of incomplete infarction. We have had a chance to see one such postpartum infarct,—death was for another reason,—which showed the typical hemorrhage and edema in the alveoli, without any destruction of the wall.

Pulmonary infarcts, then, can occur in anyone and the outcome depends not on the size of the embolus but on the previous condition of the lung.

#### PULMONARY EMBOLI: RADIOLOGICAL ASPECTS Dr. Aubrey O. Hampton

We have been able to demonstrate that the antemortem and postmortem films of the lung are essentially the same, for the fundamental physical principles are unchanged. Acute infarcts contain air, so we do not see a dense shadow, and for this reason such shadows are difficult to interpret. X-rays of infiltrated lungs show infarction shadows better, usually with a convexity toward the lung root. All infarcts occur where two pleural surfaces meet. Almost none are triangular in shape but conform to the shape of the portion of lung infarcted. True infarcts which heal usually leave a linear scar with a slight dimple at the pleural surface.

This study has taught us to differentiate complete and incomplete infarction and to realize that the latter is much commoner than we thought. Many people who come to the clinic with a history of pleurisy and hemoptysis and have an x-ray shadow which clears rapidly are diagnosed as having tuberculosis. Subsequent check has shown a phlebitis and a course consistent with pulmonary infarction.

#### IN VITRO DISSOLUTION OF KIDNEY STONES Dr. Fuller Albright

Renal stones are composed of an organic matrix and a precipitated crystalloid. If the crystalloid is removed the

## NOTICES

MASSACHUSETTS CENTRAL  
HEALTH COUNCIL

The annual meeting of the Massachusetts Central Health Council will be held in the Sheraton Salon of the Hotel Sheraton, 91 Bay State Road, Boston, Thursday evening, February 16, at 7 00 The Honorable Christian D Herter, speaker of the House of Representatives, will speak on Legislative Procedure

The usual business meeting and election of officers will be held

## SAMUEL D GROSS PRIZE

The Samuel D Gross Prize of the Philadelphia Academy of Surgery, amounting to fifteen hundred dollars, will be awarded in 1940 The conditions annexed by the testator are that the prize shall be awarded every five years to the writer of the best original essay, not exceeding one hundred and fifty printed pages, octavo, in length, illustrative of some subject in surgical pathology or surgical practice founded upon original investigations, the candidates for the prize to be American citizens

It is expressly stipulated that the competitor who receives the prize shall publish his essay in book form, and that he shall deposit one copy of the work in the Samuel D Gross Library of the Philadelphia Academy of Surgery, and that on the title page it shall be stated that to the essay was awarded the Samuel D Gross Prize of the Philadelphia Academy of Surgery

The essays, which must be written by a single author in the English language, should be sent to the Trustees of the Samuel D Gross Prize of the Philadelphia Academy of Surgery, care of the College of Physicians, 19 S 22d Street, Philadelphia, on or before January 1, 1940

Each essay must be typewritten, distinguished by a motto, and accompanied by a sealed envelope bearing the same motto, containing the name and address of the writer No envelope will be opened except that which accompanies the successful essay

The committee will return the unsuccessful essays if reclaimed by their respective writers, or their agents, within one year The committee reserves the right to make no award if the essays submitted are not considered worthy of the prize.

MEDICAL CLINIC AT THE PETER BENT  
BRIGHAM HOSPITAL

At 3 30 p m on Thursday, February 16, in the amphitheater of the Peter Bent Brigham Hospital, Dr Marshall N Fulton, associate in medicine, Harvard Medical School, and physician, Peter Bent Brigham Hospital, will give a medical clinic Practitioners and medical students are cordially invited to attend.

## HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Tuesday, February 14, in the Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance) at 8 15 p m

## PROGRAM

Presentation of cases

Forsan et Haec Olim Meminisse Juvabit<sup>2</sup> Dr Reginald Fitz.

Medical students and physicians are cordially invited to attend

ROBERT M ZOLLINGER, M D, *Secretary*

## HARVARD MEDICAL SCHOOL

A lecture on 'The Physiological Effects of Compressed Air' will be given by Dr Edgar M. End, of Marquette University School of Medicine, in Amphitheater C of the Harvard Medical School, on Tuesday, February 14, at 5 00 p m

NEW ENGLAND SOCIETY  
OF PHYSICAL MEDICINE

The regular meeting of the New England Society of Physical Medicine will be held at the Hotel Kenmore, Boston, on Wednesday evening, February 15, at 8 o'clock. The Council will meet at 6 00, and this will be followed by an informal dinner at 6 30

Dr C Guy Lane will speak on 'Indications for the Use of Physical Agents in Dermatology' This will be followed by general discussion

All members of the medical profession are cordially invited to attend

WILLIAM D McFEE, M D, *Secretary*

NEW ENGLAND PATHOLOGICAL  
SOCIETY

The next regular meeting of the New England Pathological Society will be held at the Massachusetts General Hospital, on Thursday, February 16, at 8 00 p m

## PROGRAM

Correlation of Postmortem Chest Teleroentgenograms with Autopsy Findings, with Special Reference to Pulmonary Embolism and Infarction. Dr Benjamin Castleman and Dr Aubrey O Hampton.

Clinical and Hematological Aspects of Early Benzol Poisoning Dr Francis T Hunter

Histological Studies of Chronic Benzol Poisoning Dr Edward A Gall and Dr Tracy B Mallory

Physicians and medical students are cordially invited to attend.

## NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Peter Bent Brigham Hospital, on Monday, February 27, at 8 15 p m

## PROGRAM

The Surgical Treatment of Patent Ductus Arteriosus Dr R. E. Gross (by invitation)

Observations on the Dynamics of the Circulation in Patent Ductus Arteriosus Dr E. P Eppinger

The Reaction of the Cardiovascular System of Dogs to Intravenous Infusion Drs R L Swank, A Yeomans and R. R. Porter (by invitation)

The Significance of Auricular Standstill Dr F F Rosenbaum (by invitation)

Some Notes on the Prognosis of Rheumatic Heart Disease. Dr S A Levine.

The discussion on the first three papers will be opened by Dr C Sidney Burwell Interested physicians and medical students are invited to attend

EDWARD F BLAND, M D, *Secretary*

## NEW ENGLAND HOSPITAL ASSOCIATION

The annual meeting of the New England Hospital Association will be held at the Hotel Statler, Boston, on Thursday Friday and Saturday, March 9 10 and 11

A G ENGELBACH M D, *Secretary*

the tumor-bearing gland was possible. In one instance a subtotal resection of the neoplastic gland was done because the other gland showed almost complete atrophy and seemed incapable of supporting life by itself.

Several instances of death from the procedure have been reported, presumably due to air embolism. We believe that we can prevent such a catastrophe by taking ten minutes to inject the air and using only half the usual amount. Our one untoward result was a large hematoma under the renal capsule from puncturing the capsule with the needle, and we believe we can now avoid such an accident. This case did not die of the injury but during a paroxysm of hypertension due to excessive secretion of adrenalin several days after the procedure.

#### ELECTRO-ENCEPHALOGRAPHY Dr Robert S Schwab

The brain is the seat of electrical activity just as is the heart, though we need four times the amplification necessary for an electrocardiogram to demonstrate this activity. Such waves were first demonstrated by placing an electrode over the occiput, with the eyes closed. When a light is flashed into the eyes the waves disappear. These waves were first called brain waves, are of low amplitude and occur about twenty times a second.

In the past two years we have taken electro-encephalograms on 960 cases. This is done by attaching three electrodes to the skin of the head and placing the patient in a metal cage which shields the instrument and patient from interfering electrical currents. In 90 per cent of the cases with clinical epilepsy we have found the typical broad, high amplitude waves, which occur about fifty times a minute. In 80 per cent of the cases showing focal clinical signs we have checked on the location of the pathologic portion of brain. Seventy five per cent of the patients with clinically diagnosed brain tumors have shown corroborative electro-encephalographic changes. The apparatus is still crude and difficult to work with and artefacts are a constant pitfall, but the method shows great promise of future value.

#### PYELITIS Dr Harold L Higgins

Pathologists have shown us that pyelitis is not an ascending infection from the bladder, nor localized to the pelvis of the kidney, but is really an interstitial inflammation—a suppurative nephritis involving the whole kidney, though the degree of involvement varies a great deal. I believe that all cases are due to partial or complete ureteral obstruction. The obstruction may be anatomical, such as one due to an aberrant renal artery, pregnant uterus, tumor, or stone, abscess or kink of the ureter, or physiological, such as one due to spasm or edema of the ureter. In acute hemorrhagic nephritis we see only red cells in the urine at first and later both red cells and leukocytes. We also get edema of the kidney causing oliguria and general body edema, hence, there is probably also edema of the ureter which may give rise to a secondary pyelitis from obstruction. Virus infections are frequently associated with edema. Such edema would probably account for the pyelitis of measles.

The chief bacteriologic agents incriminated in pyelitis are the intestinal bacteria, such as *Bacillus coli* and *Streptococcus faecalis*. The kidneys probably eliminate these organisms physiologically at times though not regularly. In the presence of such a set up, obstruction and stasis will result in ordinarily harmless bacteria becoming pathogens and giving rise to inflammation.

Treatment with sulfanilamide reduces the virulence of the organism, and if the obstruction is meanwhile relieved, the patient is cured. If not, we get a recurrence

when the drug is stopped. Mandelic acid per se probably does nothing, but the limitation of fluids and the attendant dehydration release obstruction by getting rid of the ureteral edema.

In general almost all cases of pyelitis are the result of obstruction to urinary outflow and associated infections due to the normal intestinal bacteria in the kidney and urine.

#### RECENT OBSERVATIONS ON CHRONIC INDUSTRIAL BENZOL POISONING Dr Francis T Hunter

To date, the literature has been filled with incomplete conflicting reports of the results of benzol poisoning. The following are some random and incomplete observations we have made in the study of 79 workers exposed to benzol. All the cases were studied by a detailed history, physical examination and a complete hematological work up. We have 7 cases with pathologic material—1 postmortem bone marrow biopsy, 1 bone marrow biopsy and 5 autopsies. In addition we have the material from 6 cases autopsied between 1920 and 1924. Certain previously known facts have been reconfirmed.

1 Fourteen cases (75 per cent) had red-cell counts above 5,200,000. The highest was 7,300,000 on three different occasions with a white-cell count of 12,000 with 63 per cent polymorphonuclears. (One week after removal from exposure his red-cell count dropped to 5,200,000.)

2 Twenty-two cases (27 per cent) showed young cells in their smears, that is, myeloblasts and normoblasts. These were workers who had not had excessive exposure and showed no signs of ill health.

3 Twenty-five per cent of the cases showed eosinophils (the highest being 23 per cent).

4 Hyperplastic bone marrow was found to be associated with the picture of aplastic anemia in the peripheral blood stream.

In addition the following new facts have come to light.

1 Anemia with an increased white-cell count may occur. Twenty-three per cent showed myeloblasts, and 6 per cent normoblasts.

2 There may be no anemia but a white-cell count as high as 45,000. The differential count shows chiefly lymphocytes and the stained smear is similar to that of a case of lymphatic leukemia. (Three months after removal from exposure the blood picture was normal.)

3 There may be a macrocytic, pernicious-anemia like picture.

4 Only in the early stages may one have an increased white-cell count with increased polymorphonuclears and the rest of the blood picture normal.

5 Marked splenomegaly and extreme hyperplasia of the bone marrow may occur.

6 In the same individual the bone marrow may be hyperplastic in some places and aplastic in others.

7 Clinical benzol poisoning may develop eight to eighteen months after removal from exposure. Presumably the bone marrow is adequate for normal life, but when placed under stress it cannot keep up.

8 Long exposure, that is, as much as twelve years, may result only in a hyperplastic bone marrow. In other patients a short exposure may cause death, with an aplastic anemia. (In mice we know that leukemia can develop long after exposure to benzol has ceased.)

The time element is important and symptoms may be delayed a long time. Hence, histories must be very detailed.

## NOTICES

MASSACHUSETTS CENTRAL  
HEALTH COUNCIL

The annual meeting of the Massachusetts Central Health Council will be held in the Sheraton Salon of the Hotel Sheraton, 91 Bay State Road, Boston, Thursday evening, February 16, at 7 00 The Honorable Christian D Herter, speaker of the House of Representatives, will speak on Legislative Procedure

The usual business meeting and election of officers will be held.

## SAMUEL D GROSS PRIZE

The Samuel D Gross Prize of the Philadelphia Academy of Surgery, amounting to fifteen hundred dollars, will be awarded in 1940 The conditions annexed by the testator are that the prize shall be awarded every five years to the writer of the best original essay, not exceeding one hundred and fifty printed pages, octavo, in length, illustrative of some subject in surgical pathology or surgical practice founded upon original investigations, the candidates for the prize to be American citizens

It is expressly stipulated that the competitor who receives the prize shall publish his essay in book form, and that he shall deposit one copy of the work in the Samuel D Gross Library of the Philadelphia Academy of Surgery, and that on the title page it shall be stated that to the essay was awarded the Samuel D Gross Prize of the Philadelphia Academy of Surgery

The essays, which must be written by a single author in the English language, should be sent to the Trustees of the Samuel D Gross Prize of the Philadelphia Academy of Surgery, care of the College of Physicians, 19 S 22d Street, Philadelphia, on or before January 1, 1940

Each essay must be typewritten, distinguished by a motto, and accompanied by a sealed envelope bearing the same motto, containing the name and address of the writer No envelope will be opened except that which accompanies the successful essay

The committee will return the unsuccessful essays if reclaimed by their respective writers, or their agents, within one year The committee reserves the right to make no award if the essays submitted are not considered worthy of the prize.

MEDICAL CLINIC AT THE PETER BENT  
BRIGHAM HOSPITAL

At 3 30 p m on Thursday, February 16, in the amphitheater of the Peter Bent Brigham Hospital, Dr Marshall N Fulton, associate in medicine, Harvard Medical School, and physician, Peter Bent Brigham Hospital, will give a medical clinic Practitioners and medical students are cordially invited to attend.

## HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Tuesday, February 14, in the Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance) at 8 15 p m

## PROGRAM

Presentation of cases

Forsan et Haec Olim Meminisse Juvabit? Dr Reginald Fitz

Medical students and physicians are cordially invited to attend.

ROBERT M ZOLLINGER, M D, *Secretary*

## HARVARD MEDICAL SCHOOL

A lecture on 'The Physiological Effects of Compressed Air' will be given by Dr Edgar M End, of Marquette University School of Medicine, in Amphitheater C of the Harvard Medical School, on Tuesday, February 14, at 5 00 p m

NEW ENGLAND SOCIETY  
OF PHYSICAL MEDICINE

The regular meeting of the New England Society of Physical Medicine will be held at the Hotel Kenmore, Boston, on Wednesday evening, February 15, at 8 o'clock. The Council will meet at 6 00, and this will be followed by an informal dinner at 6 30

Dr C Guy Lane will speak on "Indications for the Use of Physical Agents in Dermatology" This will be followed by general discussion

All members of the medical profession are cordially invited to attend

WILLIAM D McFEE, M D, *Secretary*

NEW ENGLAND PATHOLOGICAL  
SOCIETY

The next regular meeting of the New England Pathological Society will be held at the Massachusetts General Hospital, on Thursday, February 16, at 8 00 p m

## PROGRAM

Correlation of Postmortem Chest Teleroentgenograms with Autopsy Findings, with Special Reference to Pulmonary Embolism and Infarction. Dr Benjamin Castleman and Dr Aubrey O Hampton.

Clinical and Hematological Aspects of Early Benzol Poisoning Dr Francis T Hunter

Histological Studies of Chronic Benzol Poisoning Dr Edward A Gall and Dr Tracy B Mallory

Physicians and medical students are cordially invited to attend

## NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Peter Bent Brigham Hospital, on Monday, February 27, at 8 15 p m

## PROGRAM

The Surgical Treatment of Patent Ductus Arteriosus Dr R. E. Gross (by invitation)

Observations on the Dynamics of the Circulation in Patent Ductus Arteriosus. Dr E P Eppinger

The Reaction of the Cardiovascular System of Dogs to Intravenous Infusion Drs R. L. Swank, A. Yeomans and R. R. Porter (by invitation)

The Significance of Auricular Standstill Dr F F Rosenbaum (by invitation)

Some Notes on the Prognosis of Rheumatic Heart Disease. Dr S A Levine.

The discussion on the first three papers will be opened by Dr C. Sidney Burwell Interested physicians and medical students are invited to attend.

EDWARD F BLAND, M D, *Secretary*

## NEW ENGLAND HOSPITAL ASSOCIATION

The annual meeting of the New England Hospital Association will be held at the Hotel Statler, Boston, on Thursday Friday and Saturday, March 9, 10 and 11

A G ENGELBACH, M D, *Secretary*

## SOCIETY MEETINGS AND CONFERENCES

## CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, FEBRUARY 13

## TUESDAY FEBRUARY 14

- \*9 10 a m Joseph H Pratt Diagnostic Hospital The Significance of Anal Bleeding Dr E. T. Whitney
- \*10 a m 12 30 p m Tumor clinic Boston Dispensary
- 5 p m Lecture on the Physiological Effects of Compressed Air Harvard Medical School Amphitheater C
- \*8 15 p m Harvard Medical Society Peter Bent Brigham Hospital Amphitheater

## WEDNESDAY FEBRUARY 15

- \*9 10 a m Joseph H Pratt Diagnostic Hospital Hospital case presentation Dr S J Thannhauser
- \*12 m Clinicopathological conference. Children's Hospital Amphitheater
- \*8 p m New England Society of Physical Medicine Hotel Kenmore

## THURSDAY FEBRUARY 16

- 8 30-9 30 a m Exchange visit Surgical and Orthopedic Staffs of the Peter Bent Brigham and Children's hospitals held this week at the Peter Bent Brigham Hospital
- \*9 10 a m Joseph H Pratt Diagnostic Hospital. Electrocardiographic Changes in Pericarditis. Dr C. P. Roberts
- \*3 30 p m Medical clinic at the Peter Bent Brigham Hospital
- 5 p m George W. Gay Lecture on Medical Ethics Harvard Medical School Amphitheater C.
- 7 p m Massachusetts Central Health Council Hotel Sheraton 91 Bay State Road.
- \*8 p m New England Pathological Society Massachusetts General Hospital

## FRIDAY FEBRUARY 17

- \*9 10 a m. Joseph H Pratt Diagnostic Hospital Differential Diagnosis of Coronary Thrombosis Dr Cadis Phipps
- \*10 a m 12 30 p m Tumor clinic Boston Dispensary
- 12 m Clinical meeting of the Children's Medical Service Massachusetts General Hospital Ether Dome
- 12 m Urological conference Massachusetts General Hospital lower outpatient amphitheater

## SATURDAY FEBRUARY 18

- 9 10 a m Joseph H Pratt Diagnostic Hospital Hospital case presentation Dr S J Thannhauser
- \*10 a m 12 m Staff rounds of the Peter Bent Brigham Hospital Conducted by Dr Henry A. Christian

## SUNDAY FEBRUARY 19

- 4 p m Illustrated public health lecture, Faulkner Hospital auditorium Girth Control Dr Arthur A. Cushing
- 4 p m Free public lecture Harvard Medical School Amphitheater of Building D The Significance of Syphilis and Other Venereal Diseases Dr William C. Quinby

## WORCESTER

MARCH 8—Worcester Memorial Hospital

APRIL 12—Worcester Hahnemann Hospital.

MAY 10—Worcester Country Club—Annual meeting

With the exception of the annual meeting in May all the meetings begin with a supper at 6 30 p m which is followed at 7 30 p m. by the business and scientific sessions

## BOOK REVIEWS

*Your Chest Should Be Flat The deep chest makes better soil for tuberculosis* S. A. Weisman. 145 pp Philadelphia, London, New York and Montreal J. B. Lippincott Co, 1938 \$2.00

The title of this small book tells practically the whole story The book deals with the physical development of the chest and points out that the deep chest makes better soil for tuberculosis

The author has approached the problem of tuberculosis from a very interesting angle, although the relation of chest development and tuberculosis has been discussed for very many years The author may be able to prove his point if he follows the group of apparently normal children in whom he found round, deep, chests, and later cites a lower incidence of tuberculosis in these patients as compared with that in those who were flat-chested. Furthermore, evidence to the effect that round chests are commonly found among those who now have and have had tuberculosis for some time would be in favor of his theory

The subject is a fascinating one, and it is hoped that the author will follow up this work and subsequently publish more facts

*Feminine Hygiene in Marriage* A. F. Niemoeller 155 pp New York Harvest House, 1938 \$2.00

This tiny volume contains little of value to anyone with a modicum of information regarding the female and her hygiene, whether such modicum was obtained through the usual medical channels or by that peculiar fate which permits one to be a female.

There is little to recommend the book to anyone in the medical profession and less to anyone not so engaged.

*Virus Diseases and Viruses* Patrick P. Laidlaw 52 pp Cambridge University Press, 1938 90 cents.

This small brochure is most readable and informative. Sir Patrick Laidlaw in the Rede Lecture of 1938 has admirably given a broad view to the study of viruses and has summarized the important advances made in this field of investigation

## EXPERIMENTAL STUDIES CONCERNING THE NATURE OF HYPERTENSION\*

### Their Bearing on Surgical Treatment

STANLEY J G NOWAK, M.D.,† AND IRVING J WALKER, M.D.‡

BOSTON

**E**XPERIMENTAL investigation into the cause of hypertension has followed two lines, one dealing with mechanisms producing increased vasomotor activity, the other with the kidney as a possible source of a hypertensive substance

#### HYPERTENSION DUE TO INCREASED VASOMOTOR ACTIVITY

*Carotid-Sinus Denervation and Aortic-Depressor Nerve Section* Attempts at producing increased vasomotor tone analogous to essential hypertension have met with success through carotid-sinus denervation and section of the aortic-depressor nerve. First described by Hering's pupils, Koch and Mies,<sup>1</sup> in the rabbit in 1929 and by Heymans<sup>2</sup> in the dog in 1931, this method has been corroborated by Kremer, Wright and Scarff<sup>3</sup> and by one of us (S J G N<sup>4</sup>). The principle underlying this experimental means for producing hypertension depends upon the interruption of afferent nerve impulses which normally buffer or depress the activity of the circulatory centers in the medulla. Removal of these impulses permits the vasoconstrictor, cardio-accelerator and adrenine-secreting centers to exert their maximal effects, with a resulting elevation of blood pressure in dogs from the average normal level of 130 mm of mercury to as high as 250 mm. The majority of these animals show oscillations in blood-pressure values similar to those frequently seen in clinical essential hypertension. It has been demonstrated that the hypertension so produced may persist for three years or more.<sup>4</sup>

The obvious advantage of using this group of animals for study is that they represent a hypertensive state due chiefly to vasoconstriction and

to a lesser extent to increased secretion of adrenine and cardiac acceleration, factors which are undoubtedly responsible for clinical essential hypertension. It should not be inferred, however, that the clinical condition is due to decreased activity or suppression of the carotid-sinus and aortic-depressor nerve mechanisms. The similarity lies in the end result rather than in the cause.

*Chronic Cerebral Anemia* The conception that acute cerebral anemia and asphyxia produce a temporary increase in blood pressure through increased vasomotor activity has been frequently demonstrated since the early days of physiology.<sup>5,6</sup> By progressive ligation of the various cerebral arteries one of us (S J G N) demonstrated for the first time that chronic cerebral anemia may result in chronic hypertension (Fig 1). The

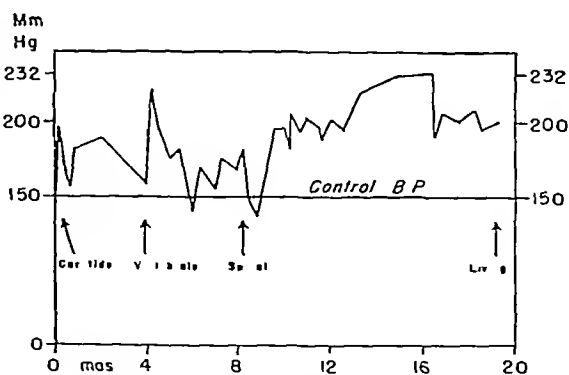

Figure 1 Hypertension Produced by Ligation of Cerebral Arteries (Dog 20)

difficulties attendant upon this experimental production of chronic hypertension lay in the extraordinary ability of the dog to re-establish practically normal cerebral circulation through well-developed anastomoses, in spite of ligation of both external and internal carotids, both vertebral arteries and the anterior spinal artery

Presented at the annual meeting of the New England Surgical Society, Boston, September 30, 1938. From the Surgical Research Laboratory and the Fifth Surgical (Harvard) Service, Boston City Hospital. Aided in part by a grant from the Permanent Charity Fund of Harvard Medical School.

†Associate in surgery, Harvard Medical School, assistant surgeon, Boston City Hospital.

‡Clinical professor of surgery, Harvard Medical School, surgeon-in-chief, Fifth Surgical (Harvard) Service, Boston City Hospital.

*Increased Intracranial Pressure* Also in line with this work are the investigations on the effect of increased intracranial pressure on arterial tension. According to Cushing,<sup>7</sup> cerebral compression produces hypertension by virtue of cerebral anemia. His observations in acute experiments and clinical studies have been confirmed by Dixon and Heller,<sup>8</sup> who have produced chronic hypertension by increasing intracranial pressure by means of injecting an inert substance, kaolin, into the fourth ventricle of rabbits.

The mechanism by which cerebral anemia stimulates the vasomotor center has been recently shown by Raab<sup>9</sup> to be due to acidosis of this center, its perfusion by acids, such as lactic acid, has resulted in acute hypertension. On the other hand, perfusion with alkaline solutions brought about a lowering of blood pressure.

*Experimental Arteriosclerosis* Handovsky and Goormaghtigh<sup>10</sup> of Heymans's laboratory have observed hypertension following the production of marked arteriosclerosis in dogs by means of the feeding of vitamin D combined with thyroidectomy. It is probable that this hypertension is due to increased activity of the vasomotor center in response to augmented peripheral resistance.

#### RENAL HYPERTENSION

Since the postulation made by Johnson<sup>11</sup> in 1868, based on clinical observations, that the diseased kidney liberates a vasoconstrictor substance, many investigators have attempted to isolate this hypertensive factor. The first of these investigations was carried out in 1898 by Tigerstedt and Bergman,<sup>12</sup> who extracted a pressor substance from normal rabbits' kidneys which they called "rennin." Similar extracts have been described by Pearce,<sup>13</sup> Bingel and Strauss<sup>14</sup> and others. Recently Landis and his co-workers<sup>15</sup> have isolated a saline kidney extract in rabbits which, on injection into normal unanesthetized rabbits, elevated the blood pressure without diminishing the skin temperature. This absence of a change in skin temperature, indicating as it does undiminished peripheral flow, is characteristic of most forms of human hypertension. It is thus distinctly different from the group of hypertensive substances such as adrenalin, tyramine, pituitrin and so forth which produce hypertension with disproportionate increase of peripheral resistance and therefore of blood flow.

Another approach to the kidney as an etiologic factor in hypertension has been the attempt to establish high blood pressure in animals by inducing changes in the kidney. These changes have been accomplished by the following methods:

- Resection of large portions of both kidneys.<sup>16</sup>
- Ligation of branches of the renal artery.<sup>17, 18</sup>
- Partial occlusion of the renal artery or its branches.<sup>19</sup>
- Partial occlusion of the renal vein.<sup>20</sup>
- Partial obstruction of the ureters.<sup>21</sup>

The outstanding experimental work in this field is that of Goldblatt and his co-workers,<sup>19</sup> who have produced a marked degree of hypertension in dogs by partially occluding the renal arteries with adjustable metal clamps. These investigators have produced striking elevations of blood pressure in their dogs, as high as 250 to 300 mm of mercury, for as long as fifteen months.

The nature of the hypertension caused by renal ischemia is revealed by the investigations of Houssay<sup>22</sup> and Blalock and Levy,<sup>23</sup> who successfully transplanted one ischemic kidney into the neck of a dog by anastomosing the renal with the carotid-jugular vessels. The development of hypertension after the transplantation and its abolition by removal of the transplanted kidney point definitely to the kidney tissue as a primary source of the pressor substance.

There is contradictory evidence as to the ability of extracts of the ischemic kidneys to produce hypertension in animals. Harrison, Blalock and Mason<sup>24</sup> and Prinzmetal and Friedman<sup>25</sup> were able to demonstrate hypertensive responses to the injection of these extracts. Page,<sup>26</sup> on the other hand, obtained entirely negative results.

That the endocrine glands are definitely concerned in hypertension of renal ischemic origin is borne out by the findings of Page and Sweet,<sup>7</sup> who showed that this type of hypertension is reduced to normal by removal of the pituitary gland. Goldblatt<sup>28</sup> and Blalock and Levy<sup>23</sup> showed that removal of both adrenal glands also causes a reduction of renoischemic high blood pressure to normal.

These important demonstrations suggest the possibility that hypertension of renal origin is due to a hormone which has its origin in either of these glands and which is activated by a substance liberated by a diseased or ischemic kidney.

#### EFFECT OF VARIOUS SYMPATHETIC PROCEDURES IN EXPERIMENTAL "ESSENTIAL" HYPERTENSION PRODUCED BY CAROTID-SINUS DENERVATION AND SECTION OF THE AORTIC-DEPRESSOR NERVE

In 1923 Daniélopou<sup>9</sup> and Brüning<sup>30</sup> made independent suggestions of the possible value of splanchnic-nerve resection in arterial hypertension. Unilateral resection for this condition was first performed in 1930 by Pieri.<sup>31</sup> In 1934 Craig and Brown<sup>32</sup> resorted to bilateral splanchnic resection. This field has been extended by Fralick

and Peet,<sup>33</sup> Smithwick,<sup>34</sup> Page and Heuer<sup>35</sup> and others

In 1930 Adson and Craig<sup>36</sup> and in 1937 Page and Heuer<sup>37</sup> resorted to extensive ventral rhizotomy in order to obtain a larger area of vasodilatation than that afforded by splanchnic section

Contemporaneously with the early work in this clinical field one of us (SJGN<sup>33</sup>) approached the rationale of partial sympathetic exclusion in dogs with denervated carotid-sinuses and sectioned aortic-depressor nerves. It was demonstrated in 1934 that bilateral splanchnic-nerve section combined with bilateral abdominal ganglionectomy failed to reduce the arterial hypertension produced by this means. In the same year Bacq, Brouha and Heymans<sup>39</sup> showed that total sympathectomy in dogs prevented the development of acute hypertension of carotid-sinus, aortic-depressor-nerve origin.

These investigations have been extended and permit further analysis. The results may be best illustrated in Dog 11 of our series (Fig 2). This

first sacral) also caused a temporary fall in pressure to 155 mm., with return to its former high level of 205 mm. after two months.

Right thoracic ganglionectomy (stellate ganglion to the eighth dorsal ganglion) two and a half months after the latter procedure caused only a slight fall in pressure (205 to 185 mm.), with a subsequent rise to 225 mm.

This dog died spontaneously five and a half months later, after three years of hypertension, with a final pressure of 205 mm.

The ineffectiveness of bilateral splanchnic-nerve section in reducing this type of hypertension was demonstrated in two other dogs. One of these (Dog 14) with an oscillating type of hypertension showed a more lasting fall in blood pressure from 200 to 156 mm for five months, with subsequent return to levels as high as 245 mm (Fig 3). In the third dog (Dog 7), bilateral splanchnic-nerve section combined with removal of the right abdominal sympathetic chain caused the blood pressure to drop temporarily from 220 to 158 mm. Two weeks later it returned to 190 mm. Nine months later it reached 235 mm (Fig 4).

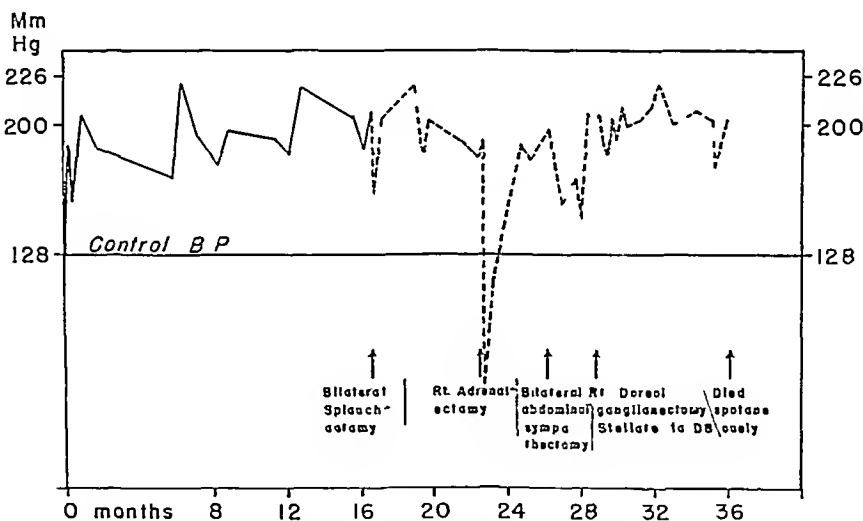

Figure 2 Effect of Sympathectomies on Blood Pressure in Chronic Hypertension Produced by Carotid-Sinus and Aortic Depressor Denervation (Dog 11)

dog showed a persistent elevation of blood pressure varying between 180 and 226 mm of mercury for seventeen months after carotid-sinus and aortic-depressor-nerve exclusion. Operative procedures on the sympathetic system showed the following effects on blood pressure:

Bilateral splanchnic section caused a drop in pressure from 205 to 170 mm of mercury which lasted only two weeks, when the pressure regained its former level, it subsequently rose to an even higher point.

Extirpation of the right adrenal gland six months later produced a marked but also temporary fall in blood pressure to 60 mm of mercury, with return to its former level of 190 mm. two months later.

Bilateral abdominal sympathectomy (first lumbar to

Heymans<sup>40</sup> showed that total sympathectomy carried out in three stages in a dog with previously denervated carotid-sinus and aortic-depressor regions and with resulting hypertension reduced the blood pressure to normal. He observed that the blood pressure still remained at its hypertensive level after three-fourths sympathectomy. This finding is in agreement with our observations on the first dog discussed, which showed a tension of 205 mm after two-thirds sympathectomy.

By reversing the procedure followed by Heymans we have demonstrated that preliminary total

sympathectomy fails to neutralize experimental chronic hypertension of carotid-sinus and aortic-depressor-nerve origin. Dog 30 was totally sympathetomized in two stages, the entire thoraco-abdominal chain being removed intact in each

fourths sympathetomy fails to affect this hypertension. Finally, the mechanism underlying this hypertension is still able to exert a moderate but definite hypertensive effect in spite of total sympathetomy. Whether, in the latter case, this increment in pressure is due to the liberation of some intrinsic factor or to the development of vasoconstriction by some unknown mechanism cannot be answered as yet. It is definitely not due to any organic change such as arteriosclerosis.

From these data one is obliged to draw the conclusion that there is little if any rationale for splanchnotomy and rhizotomy in clinical essential hypertension.

EFFECT OF VARIOUS SYMPATHETIC PROCEDURES ON  
EXPERIMENTAL HYPERTENSION PRODUCED  
BY RENAL ISCHEMIA

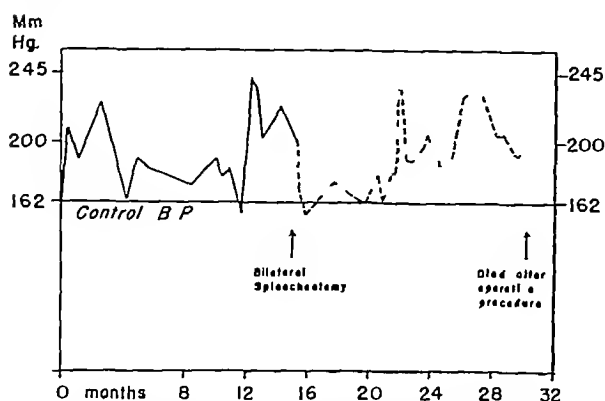

Figure 3 Effect of Sympathectomies on Blood Pressure in Chronic Hypertension Produced by Carotid-Sinus and Aortic Depressor Denervation (Dog 14)

stage, thus eliminating any known sympathetic activity. The control blood pressure was 116 mm. One and a half months after total sympathetomy the carotid-sinuses were denervated and the aortic-depressor nerves sectioned. This procedure was

The effect of partial and total sympathetomy on the nephroschemic hypertension is, as one would expect, completely negative. In this type of hypertension the underlying mechanism is a vasoconstrictor substance liberated by an ischemic kidney which acts on the peripheral vascular musculature. In the presence of this intrinsic stimulus the blood vessels obviously cannot respond to a neurogenic vasodilator mechanism.

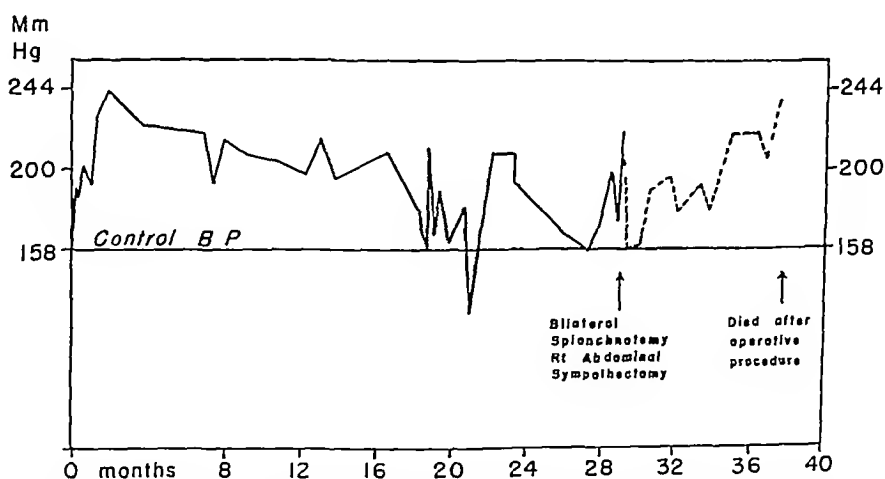

Figure 4 Effect of Sympathectomies on Blood Pressure in Chronic Hypertension Produced by Carotid-Sinus and Aortic Depressor Denervation (Dog 7)

followed by a definite and sustained elevation of blood pressure to 170 mm. The dog died spontaneously two and a half months after denervation, with a blood pressure of 160 mm (Fig 5).

Thus bilateral splanchnotomy fails to reduce, except temporarily, a type of experimental hypertension which is preponderantly, if not purely, vasomotor in origin. In fact, two thirds to three-

These views are based on the demonstration by Page<sup>42</sup> that denervation of the kidneys does not alter the course of nephroschemic hypertension. Goldblatt<sup>42</sup> showed further that bilateral splanchnotomy is likewise ineffective. In fact, total sympathetomy has failed to affect this hypertension, as shown by Freeman and Page<sup>43</sup> and Heymans et al.<sup>44</sup>

# EFFECT OF NEPHRECTOMY IN HYPERTENSION DUE TO UNILATERAL ISCHEMIA AND PYELONEPHRITIS

The successful results of nephrectomy in unilateral pyelonephritis as reported by Butler<sup>15</sup> and others is in keeping with the results of Goldblatt<sup>28</sup> and others who have abolished hypertension of unilateral renal ischemic origin by removal of the

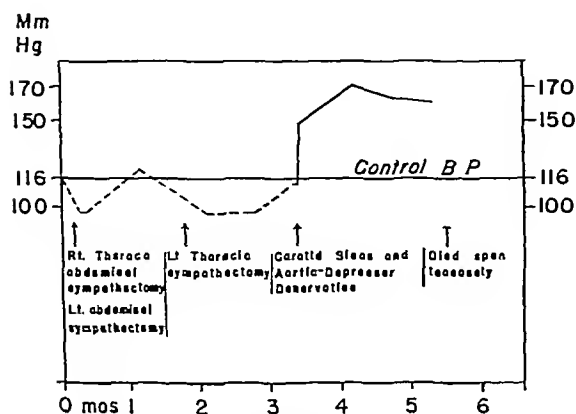

Figure 5 Effect of Carotid-Sinus and Aortic-Depressor Denervation on the Blood Pressure in a Totally Sympathectomized Dog (Dog 30)

ischemic kidney. This important observation should stimulate clinicians to make a careful search for the possibility of unilateral renal disease in hypertensive patients and to give serious consideration to nephrectomy.

## SUMMARY

Various experimental methods which produce hypertension are discussed.

Corroboration of carotid-sinus denervation and aortic-depressor-nerve section as a means of producing experimental hypertension through increased vasomotor activity is presented.

The production of chronic hypertension by chronic cerebral anemia as an original demonstration is presented.

The nature of experimental hypertension due to renal ischemia is discussed in the light of recent investigations.

Partial sympathectomy, including bilateral splanchnotomy, unilateral adrenalectomy, bilateral lumbar ganglionectomy and even two-thirds to three-fourths sympathectomy, fails to reduce hypertension of carotid sinus and aortic-depressor-nerve origin.

Preliminary total sympathectomy does not prevent the establishment of moderate hypertension of carotid sinus and aortic-depressor nerve origin. These results in an experimental form of hyper-

tension identical with clinical essential hypertension indicate that bilateral splanchnotomy and ventral rhizotomy lack rational grounds for their use in essential hypertension.

sympathectomy fails to neutralize experimental chronic hypertension of carotid-sinus and aortic-depressor-nerve origin. Dog 30 was totally sympathectomized in two stages, the entire thoraco-abdominal chain being removed intact in each

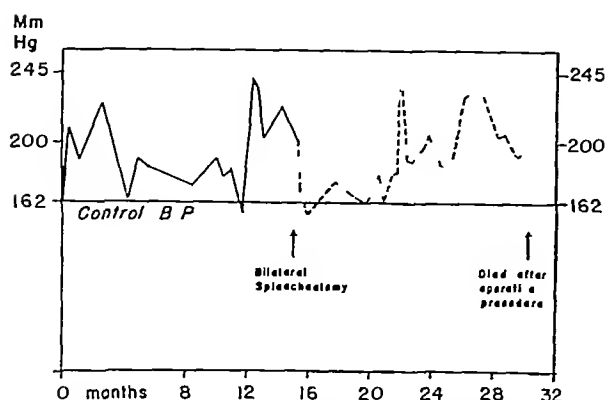

Figure 3 Effect of Sympathectomies on Blood Pressure in Chronic Hypertension Produced by Carotid-Sinus and Aortic Depressor Denervation (Dog 14)

stage, thus eliminating any known sympathetic activity. The control blood pressure was 116 mm. One and a half months after total sympathectomy the carotid-sinuses were denervated and the aortic-depressor nerves sectioned. This procedure was

fourths sympathectomy fails to affect this hypertension. Finally, the mechanism underlying this hypertension is still able to exert a moderate but definite hypertensive effect in spite of total sympathectomy. Whether, in the latter case, this increment in pressure is due to the liberation of some intrinsic factor or to the development of vasoconstriction by some unknown mechanism cannot be answered as yet. It is definitely not due to any organic change such as arteriosclerosis.

From these data one is obliged to draw the conclusion that there is little if any rationale for splanchnotomy and rhizotomy in clinical essential hypertension.

#### EFFECT OF VARIOUS SYMPATHETIC PROCEDURES ON EXPERIMENTAL HYPERTENSION PRODUCED BY RENAL ISCHEMIA

The effect of partial and total sympathectomy on the nephroischemic hypertension is, as one would expect, completely negative. In this type of hypertension the underlying mechanism is a vasoconstrictor substance liberated by an ischemic kidney which acts on the peripheral vascular musculature. In the presence of this intrinsic stimulus the blood vessels obviously cannot respond to a neurogenic vasodilator mechanism.

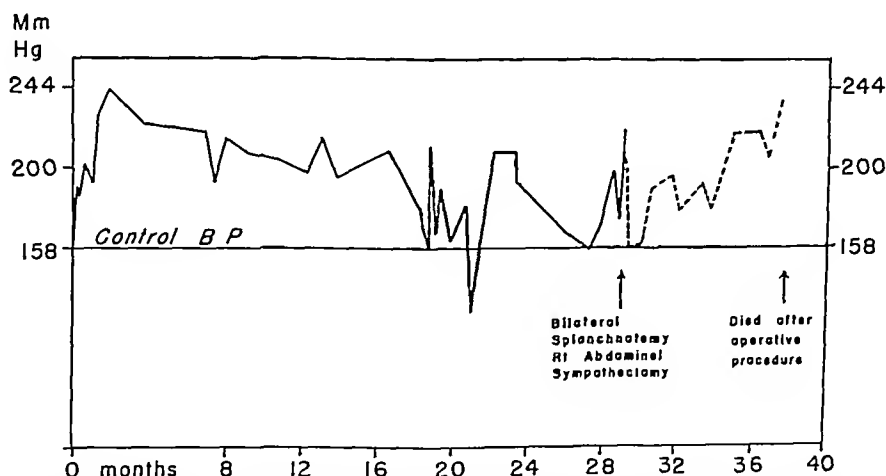

Figure 4 Effect of Sympathectomies on Blood Pressure in Chronic Hypertension Produced by Carotid-Sinus and Aortic Depressor Denervation (Dog 7)

followed by a definite and sustained elevation of blood pressure to 170 mm. The dog died spontaneously two and a half months after denervation, with a blood pressure of 160 mm (Fig 5).

Thus bilateral splanchnotomy fails to reduce, except temporarily, a type of experimental hypertension which is preponderantly, if not purely, vasomotor in origin. In fact, two thirds to three

These views are based on the demonstration by Page<sup>11</sup> that denervation of the kidneys does not alter the course of nephroischemic hypertension. Goldblatt<sup>12</sup> showed further that bilateral splanchnotomy is likewise ineffective. In fact, total sympathectomy has failed to affect this hypertension, as shown by Freeman and Page<sup>13</sup> and Heymans et al.<sup>14</sup>

using preserved dissection-room cadavers have usually described the plexus as a conglomerate nerve without separation and without anastomosing fibers. Experimentally, on animals, and by stimulation during operation on human beings, it has been shown that the thoracolumbar nerves supply the region of the trigone more exclusively with fibers

to the hypogastric (pelvic) ganglia. As they emerge from these, the fibers can be divided again into three groups, the upper root supplying the fundus of the bladder, the middle root supplying the mid-portion of the bladder, and the lower root going to the lower aspect of the bladder, the vesical neck and the adjacent urethra.

Table 1 *Reported Cases of Tuberculosis of the Bladder Treated by Sympathetic Surgery*

CASE NO.	AUTHOR	REMARKS	OPERATION	RESULTS
1	Learmonth <sup>7</sup>	Age 33	Presacral neurectomy	Marked relief of pain only slight frequency
2	Learmonth <sup>11</sup>	Age 45 tuberculosis of genitourinary tract for 5 years.	Cutting of efferent branches of hypogastric ganglia and presacral neurectomy	Died postoperatively
3		Age 35 tuberculosis for 6 years nephrectomy	Presacral neurectomy	Condition good 6 months then return of symptoms.
4	Learmonth and Braasch <sup>12</sup>	Age 35 (woman) 5 years of urinary frequency and severe pain.	Presacral neurectomy	Disappearance of pain persistence of frequency
5	Bochet <sup>4</sup>	Unilateral crisis type of pain	Periureteral sympathectomy (unilateral)	Relieved unilateral crises until death in 4 months
6		Pain originating from ureteral stump	Periureteral sympathectomy (unilateral)	Lived 2 years relief.
7		Bilateral type of crisis pain	Periureteral sympathectomy (bilateral)	Complete relief
8	Van Duien <sup>13</sup>	Genitourinary tuberculosis	Presacral neurectomy	Persistent pain and incontinence
9	Perrin <sup>14</sup>	Severe dysuria	Presacral neurectomy	Immediate amelioration of frequency died 3 months postoperatively
10		Severe pain and frequency	Presacral neurectomy	No pain died 15 days postoperatively
11		Frequency to point of incontinence; severe dysuria.	Presacral neurectomy	Amelioration of frequency
12	Pieri <sup>15</sup>	Age 40 nephrectomy for tuberculosis	Presacral and hypogastric neurectomies	Some relief of pain for 4 years
13		Age 16 severe pain and frequency	Presacral neurectomy division of sympathetic chain and rami communicantes.	Excellent relief of pain 2 years until death
14		Age 36 tuberculosis of lungs and urinary tract pain and frequency	Presacral neurectomy division of sympathetic chain and rami communicantes	Died in 4 days of uremia apparent relief of pain
15	Reynard and Mahon <sup>16</sup>	Operated on five times for tuberculosis of urinary tract	Presacral and hypogastric neurectomy	Relief only after resection of ulcer in bladder
16	von Suermondt Leiden <sup>17</sup>	No history	Presacral neurectomy	Less frequency
17		No history	Presacral neurectomy	Less frequency
18		No history	Presacral neurectomy	Less frequency

## PELVIC SYMPATHETIC SURGERY FOR THE RELIEF OF BLADDER PAIN\*

### Resection of the Superior Hypogastric Plexus and Lateral Sacral Sympathetic Ganglia in Tuberculous Cystitis

CARLISLE F SCHROEDER, M.D

DETROIT, MICHIGAN

THE purpose of this paper is to give a brief outline of the treatment of intractable pain of tuberculous cystitis by sympathetic denervation of the pelvis. A brief résumé of the history, anatomy and physiology of the nerves involved will be presented in order to give the chronological background.

The superior hypogastric nerve plexus of the pelvis was first described by Winslow<sup>1</sup> in 1732, and has been redescribed and renamed many times since. Jaboulay<sup>2</sup> in 1899 first directed attention toward relief of pain by surgery of the pelvic sympathetic nerves. He used a retrorectal approach which probably destroyed the nerve pathways to or from the hypogastric ganglia, resulting in urinary incontinence, and the operation did not meet with approval. Latarjet<sup>3</sup> in 1913 first adequately described the pelvic sympathetic nerves, but erroneously named the superior hypogastric plexus the "presacral nerve." In 1921 Rochet,<sup>4</sup> attempting to relieve pain in tuberculous cystitis, used periureteral sympathectomies on 3 patients with some relief, but all had an associated incontinence of urine, as did Jaboulay's operated patients, and probably for the same reason. Cotte<sup>5</sup> first performed the operation known as presacral neurectomy in 1925, and has since popularized it with the medical profession, especially gynecologists. Pieri<sup>6</sup> in 1926 attempted to relieve the pain of incurable tuberculous cystitis by the use of Cotte's operation (excision of the superior hypogastric plexus), but was only partially successful. He then did a more radical neurectomy by incising the lateral sacral chains at the level of the first sacral

segment, and also cut the rami communicantes to the sacral chain, with better results. In 1932 Learmonth<sup>7</sup> applied Cotte's operation to neurogenic imbalance of the bladder.

Anatomically the nerve supply of the bladder has two subdivisions, the somatic and the autonomic. The latter is composed of the sympathetic and the parasympathetic systems. The somatic nerves take their origin from the anterior division of the third and fourth sacral nerve roots, and carry both motor and sensory fibers to the bladder and posterior urethra. The sympathetic nerves are derived from the thoracolumbar system. Their origin is spread over a large area of the cord, that is, from the celiac, renal and mesenteric abdominovisceral ganglia, as well as from the first four lateral lumbar sympathetic chain ganglia. All these fibers are bottle-necked in the region of the last lumbar vertebral body as the superior hypogastric plexus (presacral nerve). This anatomical peculiarity makes the fibers easily amenable to surgery, even though their origin is so widespread segmentally over the cord. The superior hypogastric plexus divides into two more or less distinct nerve groups, that is, the right and left hypogastric nerves, which carry the thoracolumbar sympathetic fibers to the hypogastric (pelvic) ganglia and hence to the bladder. The superior hypogastric plexus and hypogastric nerves during their course receive branches from other sources from the last lumbar sympathetic ganglia, from the plexus surrounding the inferior mesenteric vessels, and their continuation, and from the superior hemorrhoidal nerve. They also receive fine filaments from the sacral chain, as shown by our own dissections on fresh cadavers and examinations of living tissue at the time of operation. Anatomists

Presented at the eighty-second meeting of the New England Branch of the American Urological Association March 3 1938

From the Department of Urology Charles Godwin Jennings Hospital Detroit Michigan

moved before the posterior peritoneum is closed. The abdomen is closed without drainage.

#### CASE REPORTS

**Case 1** M. D., a 12-year-old girl, gave a 6-year history of urinary tuberculosis, confirmed by guinea pig inoculation. There was voiding every half hour, with incontinence at night. The bladder capacity was 80 cc. Excision of the superior hypogastric plexus and lateral sacral chains was performed July 3, 1934. The bladder capacity

the bladder capacity increased to 290 cc. and continued at 300 cc.

**Case 4** R. B., a 42-year-old man, had a 24 year history of bone and joint tuberculosis, with a diagnosis of genitourinary tuberculosis 7 years previously. The patient had voided every 15 minutes with severe pain for the last 2 months. Guinea pig inoculations were positive. Resection of the superior hypogastric plexus and lateral sacral chains was done in November, 1934. There was no further pain, the patient voided every 2½ or 3 hours, with a bladder capacity of 175 cc.

**Case 5** A. B., a 48-year-old man, 4 years previous to examination had had painful and frequent urination, 10 months previously hematuria had developed, followed by bilateral tuberculous epididymitis and increased bladder symptoms, so that he voided every 15 minutes, with a bladder capacity of 100 cc. A diagnosis of renal tuberculosis was made and was confirmed by guinea pig inoculation. Excision of the superior hypogastric plexus and the lateral sacral chains was followed by a rise in bladder capacity to 275 cc., with frequency decreased to every 2 or 3 hours.

**Case 6** A. G., a 26-year-old woman, underwent a nephrectomy for tuberculosis in February, 1934, with no relief of bladder symptoms. Frequency and dysuria persisted in spite of hysterectomy for fibroids. There was voiding every 5 to 15 minutes. Excision of the superior hypogastric plexus and left lateral sacral chain was done in December, 1935. The bladder capacity rose to 300 cc., but the same pain persisted and there were periods during which the frequency recurred. Intrathecal alcohol was injected in April, 1936. This was followed by complete relief of pain and of frequency. The patient now voids every 3 to 4 hours during the day and twice each night.

**Case 7** R. M., a 32-year-old woman, underwent a nephrectomy for tuberculosis in 1930, with some relief of bladder symptoms for 6 years. This was followed by recurrence, the symptoms becoming unbearable. Tuberculosis was found in the remaining kidney. There was voiding every 15 or 20 minutes, with pain referred to the urethra. Excision of the superior hypogastric plexus and the lateral sacral chains was done in September, 1937, with relief of pain except that referred to the urethra. Injection of intrathecal alcohol in February, 1936, was followed by complete relief. The bladder capacity increased to 400 cc., and frequency decreased to every 3 or 4 hours.

#### COMMENT

We have delayed reporting this series of cases until the results seemed relatively permanent. Relief of frequency following pelvic sympathectomy is at times greater than the increased bladder capacity, showing decreased bladder irritability, as well as relief of pain. Healing of the bladder lesions following operation may be coincident with the increased blood supply and tissue nutrition associated with postoperative vasodilatation. Relief of pain has been uniformly successful, especially where lesions are confined to the trigone (Tuberculous bladder lesions are most frequently found about the ureteral orifices and trigone). It has been noted in our cases of bladder pain due to other conditions than tuberculosis that results are

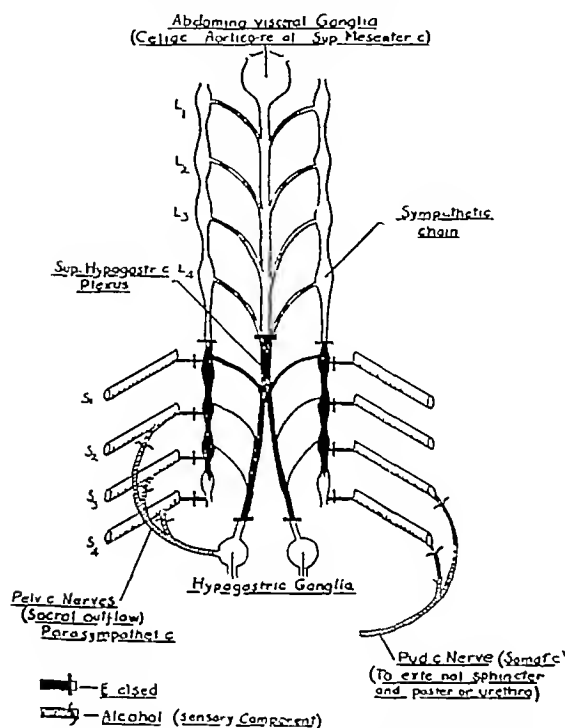

Figure 1. Excision of Superior Hypogastric Plexus, Exeresis of Sacral Sympathetic Chains and Intrathecal Alcohol Injection

increased to 180 cc., with no pain or incontinence. There was voiding every 2 hours. The patient was able to attend school for the first time in 6 years.

**Case 2** A. F., a 26-year-old man, gave a 3-year history of symptoms of genitourinary tuberculosis. There were bilateral destructive lesions of the kidneys. A guinea pig inoculation of urine from the bladder was positive. The bladder capacity was 90 cc., and there was voiding every half hour. Resection of the superior hypogastric plexus and right lateral sacral chain was done in October, 1934. Relief of pain followed and frequency ceased. The bladder capacity was increased to 175 cc., without pain, and the patient was able to work as an apprentice printer.

**Case 3** J. C., an 18-year-old girl, gave a long history of bone and joint tuberculosis. There was a 15 month history of severe dysuria and frequency, during which the patient had led a "catheter life" in a sanatorium. Cystoscopy, with pyelograms and guinea pig inoculation revealed bilateral tuberculosis. Resection of the superior hypogastric plexus and lateral sacral chains was performed in November, 1934. There was complete relief of pain.

traction of the trigone, closure of the internal sphincter, contraction of the prostate, seminal vesicles and ducts, inhibition of the expulsive power of the bladder, and that they carried afferent fibers for sensation of pain in the bladder." Recent work by other observers, especially McCrae and MacDonald,<sup>9</sup> raises doubt whether either system is exclusively excitator or inhibitor in function or whether they are antagonistic, but suggests that they do work together, along with the somatic nerves, in the regulation of bladder function. The parasympathetic fibers are apparently the most important and carry the stronger impulses.

With the reports of cases operated on for the relief of bladder pain in tuberculous cystitis, as summarized in Table 1, and with the foregoing anatomical facts and physiological observations in mind, we attempted to improve the results, and planned a more radical sympathectomy than Cotte's presacral resection and Pieri's addition of section of the sacral chains and rami communicantes. To accomplish this, we excised the superior hypogastric plexus, as did Cotte, sectioned the lateral sacral chains, as did Pieri, and then performed an exeresis of these lateral sacral chains. Just as the operation of phrenico-exeresis as proposed by Felix<sup>10</sup> causes a more marked and permanent paralysis of the diaphragm, so this operation results in a more marked and permanent relief of pain in the bladder. We still leave intact, however, the parasympathetic fibers, as well as the pudendal somatic supply. In order to remove the sensory fibers of both these groups, and not the motor fibers, which has always been done with nerve resections resulting in incontinence (Jaboulay<sup>2</sup> and Rochet<sup>4</sup>), we have added, when necessary, the postoperative use of intrathecal alcohol, with exacting control of the subarachnoid dispersion of the alcohol, the injection results in no motor paralysis, but does give complete relief of pain.

It has previously been pointed out that fibers which comprise the superior hypogastric plexus are diffused over a large area of the cord, and are therefore not well adapted to treatment with intrathecal alcohol, yet they are readily accessible to the surgeon, since anatomically they are converged in a small, easily accessible space.

Intrathecal alcohol therapy though simple is not without danger, and numerous accidents and sequelae have been recorded, it should be used only as a last resort. Its greatest danger is its relative simplicity. A spinal tap is carried out as low down as possible, with the patient in the lateral prone position. The hips are then elevated on firm pillows, or, better, by lowering the head end of the

flat supporting surface, and the torso is rotated anteriorly into an oblique position, since only the most caudal sensory (posterior) nerve components are to be primarily affected. One half to 1 cc of absolute alcohol is slowly injected. The needle is removed, and the patient is kept in this exaggerated position for three hours and in a prone position for three more. A lapse of one or two weeks is allowed between injections, that is, before intrathecal alcohol is again used, with the opposite side uppermost.

The technic of simple excision of the superior hypogastric plexus has been frequently given in the literature and will not be repeated here, except to state that it must be complete. It is a good rule to consider in surgery that in all cases the group consists of a plexus rather than a nerve, so that the smallest fiber is not overlooked and left undivided at operation. The technic of resection of the lateral sacral chains is not difficult and can be approached through the same incisions. A lower abdominal midline incision is carried out and the peritoneum opened. The entire bowel except the lower sigmoid is pushed into the upper abdomen, so that the inverted V made by the branches of the common iliac vessels is in view. Identification of the contents of the mesentery of the sigmoid is important, both for nerve fibers to and from the superior hypogastric plexus, and to avoid injury to the inferior mesenteric vessels. The posterior peritoneum is opened longitudinally in the mid-line over the bifurcation of the great vessels for a distance of 7 to 10 cm down into the concavity of the sacrum. The superior hypogastric plexus is identified and dissected well down, so that the hypogastric nerves are exposed, and all fibers leading to and from the group are disrupted, dissection being aided with nerve hooks. The nerve group is next excised, and the cut ends are tied or silver-clipped. The posterior peritoneal flaps are dissected further laterally to a point just lateral to the anterior sacral foramina. The latter are important landmarks, since the sacral sympathetic chains run just medial to the foramina and can be easily felt and "snapped" between the finger and sacrum, as is the vas deferens between the fingers and thumb. The chain is then incised above the first sacral segment, and the distal cut end is grasped with a clamp, which is twisted, curling the nerve chain over its end, at the same time the chain is pulled out. With a blunt dissector the chain is freed simultaneously of all its connections so that it can be pulled out more readily. Two or three ganglia are obtained and bleeding is scant, being easily controlled with packs, which are re

cause of death in diabetes from coma to arteriosclerosis. Of 342 deaths reported during the Naunyn era, from 1894 to 1914, 15 per cent were caused by arteriosclerosis in some form and 61 per cent by coma. Of 805 deaths reported during the Allen era, from 1914 to 1922, 26 per cent were attributed to arteriosclerosis and 42 per cent to coma. Since the discovery of insulin in 1922 (Banting era), of the 979 deaths recorded up to 1929, 44 per cent came from arteriosclerosis and 17 per cent from coma, of a total of 474 deaths from 1926 to 1929, 48 per cent were traceable to arteriosclerosis and only 11 per cent to coma.

Table 1 *Percentages of Deaths in Diabetes Due to Arteriosclerosis and to Diabetic Coma in Each of the Important Eras of Treatment*<sup>7</sup>

ERA	TOTAL DEATHS	DEATHS FROM ARTERIOSCLEROSIS %	DEATHS FROM COMA %	AVERAGE DURATION OF DIABETES yr
Naunyn—1894 to 1914	342	15	61	4.7
Allen—1914 to 1922	805	26	42	5.4
Banting—1922 to 1929	979	44	17	8.1
1922 to 1926	505	40	22	7.6
1926 to 1929	474	48	11	8.7

The evidence from all sources points obviously to arteriosclerosis as the real menace threatening the diabetic patient, but why he should be more vulnerable to cardiovascular changes than a person without the disease is still unknown. However, investigators have for some time suspected that improper fat metabolism is of sufficient importance to merit thorough study, and there is ample evidence justifying that suspicion.

The thick and milky appearance of blood drawn from a patient with diabetes was a common observation when bloodletting was in vogue. Its significance, however, aroused very little comment, and was obviously lost sight of until Fischer<sup>8</sup> in 1903 made a similar observation. He concluded that the blood lipoids were elevated in diabetes. Bloor,<sup>9</sup> after studying a group of cases from Joslin's clinic, corroborated Fischer's contention. A similar study by Gray<sup>10</sup> on 171 patients revealed very high blood-fat values in 78 per cent of the cases, and after correlating the high-fat values with the duration of life in the fatal cases he concluded that they were of grave prognostic significance. Today, such a gloomy outlook is not justified because of the stabilizing effect of insulin on blood cholesterol.

Rabinowitch<sup>11</sup> believes that there is a definite relation between high blood-lipoid values and cardiovascular disease, especially among younger diabetic patients. His study revealed that those who showed evidence of cardiovascular damage invariably had high blood-cholesterol values. Re-

cently, Leary<sup>12</sup> confirmed the observations of earlier investigators<sup>13, 14</sup>. By feeding cholesterol to rabbits he succeeded in producing lesions simulating human atherosclerosis, and he regards this phenomenon as a specific disorder of the cholesterol metabolism.

Obviously, any study which deals with the etiology of arteriosclerosis should include blood-cholesterol determinations. It is interesting to contrast the blood-lipoid values as reported by investigators<sup>9, 10</sup> prior to the insulin era with those reported since the use of insulin and better diets<sup>15, 16</sup>. Already there are indications, or at least assumptions, that the incidence of arteriosclerosis is on the decline. Shepardson<sup>17</sup> believes that the reduced incidence parallels the reduction of lipemia since the advent of insulin therapy.

For the early diagnosis of arteriosclerosis, however, no one method is sufficient. The manifestations are varied and many. The detection of cardiovascular disease is best studied from various angles. A roentgenological study of the cardiovascular system is very helpful. Bowen and Koenig<sup>18</sup> have been able to demonstrate vascular changes in the lower extremities in 63 per cent of patients beyond the age of forty. In a similar study by Morrison and Bogan,<sup>19</sup> a total of 162 observations revealed the following interesting fact: the longer the duration of the diabetes the greater the incidence of arteriosclerosis. Forty per cent of those who had had diabetes for five years showed evidence of arteriosclerosis, and the percentages for the ten-, fifteen- and twenty-year groups were 50, 83 and 92 respectively.

For additional methods the reader is referred to papers by other authors. The procedures for studying the degree of vascular disease are, singly or in combination, the oscillometer, the response to a cutaneous injection of a diluted solution of histamine, palpation of the pulsations of the dorsalis pedis and posterior tibial arteries and examination of the fundi and retinal vessels.

In this report an attempt is made to evaluate the merits of the various tests and to ascertain the virtue of supplementing one with another. One hundred cases selected at random from the Diabetic Clinic at the Rhode Island Hospital were studied. Blood-sugar and blood-cholesterol determinations were made in each case. The extremities were x-rayed and the degree of calcification was noted. The fundi, especially the retinal vessels, were studied and for the sake of uniformity were all examined by the same physician, Dr. Harry C. Messinger. The pulsations of the dorsalis pedis and posterior tibial arteries were recorded and the degree of pulsation was noted as absent, +, ++, +++ and ++++. Oscillo-

less striking, especially in cases of interstitial cystitis where the lesions are not on the trigone. This brings up again the difference in the anatomical distribution of the nerves, as stated earlier, in such cases, excision of the superior hypogastric plexus is not sufficient to bring about relief of pain. We are now using radical excision of the pelvic sympathetics along with the intrathecal injection of alcohol in all cases of interstitial cystitis, but the series is not large enough nor the individual cases of long enough duration to permit the drawing of conclusions. The results are, however, very gratifying.

#### CONCLUSIONS

Sympathetic surgery for the relief of bladder pain in incurable tuberculous cystitis is a rational procedure.

The results of excision of the superior hypogastric plexus and lateral sacral chains show significant and lasting improvement, in contradistinction to cases with less complete denervation reported in the literature.

The intrathecal injection of alcohol, with controlled subarachnoid dispersion, in connection with surgery gives a complete sensory denervation, without incontinence.

## VARIOUS METHODS OF DETERMINING THE EARLY DIAGNOSIS OF ARTERIOSCLEROSIS IN DIABETES\*

LOUIS I. KRAMER, M.D.†

PROVIDENCE, RHODE ISLAND

IT IS evident from the literature that the chief cause of death in diabetes has shifted from coma to arteriosclerosis. Joslin<sup>1</sup> reports an increase in the death rate from vascular disease, since the advent of insulin, from 28 to 47 per cent, and in a more recent study he<sup>2</sup> asserts that in a series of 42 deaths in cases of diabetes none were attributed to coma, but 50 per cent were due to vascular disease. One reason for this change is the fact that the diabetic patient's life expectancy has been increased, so that he is likely to live long enough to develop normal physiopathologic changes including arterial changes. Unfortunately there is a much graver reason—an unknown factor which seems to be inherent in the patient with diabetes, making the vessels vulnerable to arterial changes in the young as well as in the old. According to Allen,<sup>3</sup> "Arteriosclerosis is present in

every patient with diabetes past middle life, and at any age, according to others, provided the disease has been present for ten years or longer." Autopsies on 52 of Joslin's<sup>1</sup> cases showed arteriosclerosis in 19 persons who had had the disease for more than five years. Wilder<sup>4</sup> in 81 autopsies on diabetic patients found an extremely high incidence of arteriosclerosis, and Warren<sup>5</sup> makes this striking statement: "I have yet to see at autopsy a diabetic, or to read a protocol of a diabetic, whose disease has lasted five years or more, free from arteriosclerosis, regardless of age." Rabinowitch, Ritchie and McKee<sup>6</sup> in a recent report of 500 carefully studied cases of diabetes, found an incidence of 62.6 per cent of cardiovascular disease, when the cases were grouped according to age, cardiovascular disease was evident in 54.7 per cent at the age of fifty or under.

Table 1 illustrates strikingly the rapidly shifting

†Visiting physician, Rhode Island Hospital, Providence.

cause of death in diabetes from coma to arteriosclerosis. Of 342 deaths reported during the Naunyn era, from 1894 to 1914, 15 per cent were caused by arteriosclerosis in some form and 61 per cent by coma. Of 805 deaths reported during the Allen era, from 1914 to 1922, 26 per cent were attributed to arteriosclerosis and 42 per cent to coma. Since the discovery of insulin in 1922 (Banting era), of the 979 deaths recorded up to 1929, 44 per cent came from arteriosclerosis and 17 per cent from coma, of a total of 474 deaths from 1926 to 1929, 48 per cent were traceable to arteriosclerosis and only 11 per cent to coma.

Table 1 *Percentages of Deaths in Diabetes Due to Arteriosclerosis and to Diabetic Coma in Each of the Important Eras of Treatment*<sup>7</sup>

ERA	TOTAL DEATHS	DEATHS FROM ARTERIOSCLEROSIS %	DEATHS FROM COMA %	AVERAGE DURATION OF DIABETES yr
Naunyn — 1894 to 1914	342	15	61	4.7
Allen — 1914 to 1922	805	26	42	5.4
Banting — 1922 to 1929	979	44	17	8.1
1922 to 1926	205	40	22	7.6
1926 to 1929	474	48	11	8.7

The evidence from all sources points obviously to arteriosclerosis as the real menace threatening the diabetic patient, but why he should be more vulnerable to cardiovascular changes than a person without the disease is still unknown. However, investigators have for some time suspected that improper fat metabolism is of sufficient importance to merit thorough study, and there is ample evidence justifying that suspicion.

The thick and milky appearance of blood drawn from a patient with diabetes was a common observation when bloodletting was in vogue. Its significance, however, aroused very little comment, and was obviously lost sight of until Fischer<sup>8</sup> in 1903 made a similar observation. He concluded that the blood lipoids were elevated in diabetes. Bloor,<sup>9</sup> after studying a group of cases from Joslin's clinic, corroborated Fischer's contention. A similar study by Gray<sup>10</sup> on 171 patients revealed very high blood-fat values in 78 per cent of the cases, and after correlating the high-fat values with the duration of life in the fatal cases he concluded that they were of grave prognostic significance. Today, such a gloomy outlook is not justified because of the stabilizing effect of insulin on blood cholesterol.

Rabinowitch<sup>11</sup> believes that there is a definite relation between high blood lipid values and cardiovascular disease, especially among younger diabetic patients. His study revealed that those who showed evidence of cardiovascular damage invariably had high blood-cholesterol values. Re-

cently, Leary<sup>12</sup> confirmed the observations of earlier investigators<sup>13, 14</sup>. By feeding cholesterol to rabbits he succeeded in producing lesions simulating human atherosclerosis, and he regards this phenomenon as a specific disorder of the cholesterol metabolism.

Obviously, any study which deals with the etiology of arteriosclerosis should include blood-cholesterol determinations. It is interesting to contrast the blood-lipoid values as reported by investigators<sup>9, 10</sup> prior to the insulin era with those reported since the use of insulin and better diets<sup>15, 16</sup>. Already there are indications, or at least assumptions, that the incidence of arteriosclerosis is on the decline. Shephardson<sup>17</sup> believes that the reduced incidence parallels the reduction of lipemia since the advent of insulin therapy.

For the early diagnosis of arteriosclerosis, however, no one method is sufficient. The manifestations are varied and many. The detection of cardiovascular disease is best studied from various angles. A roentgenological study of the cardiovascular system is very helpful. Bowen and Koenig<sup>18</sup> have been able to demonstrate vascular changes in the lower extremities in 63 per cent of patients beyond the age of forty. In a similar study by Morrison and Bogan,<sup>19</sup> a total of 162 observations revealed the following interesting fact: the longer the duration of the diabetes the greater the incidence of arteriosclerosis. Forty per cent of those who had had diabetes for five years showed evidence of arteriosclerosis, and the percentages for the ten-, fifteen- and twenty-year groups were 50, 83 and 92 respectively.

For additional methods the reader is referred to papers by other authors. The procedures for studying the degree of vascular disease are, singly or in combination, the oscillometer, the response to a cutaneous injection of a diluted solution of histamine, palpation of the pulsations of the dorsalis pedis and posterior tibial arteries and examination of the fundi and retinal vessels.

In this report an attempt is made to evaluate the merits of the various tests and to ascertain the virtue of supplementing one with another. One hundred cases selected at random from the Diabetic Clinic at the Rhode Island Hospital were studied. Blood-sugar and blood-cholesterol determinations were made in each case. The extremities were x-rayed and the degree of calcification was noted. The fundi, especially the retinal vessels, were studied and for the sake of uniformity were all examined by the same physician, Dr. Harry C. Messinger. The pulsations of the dorsalis pedis and posterior tibial arteries were recorded and the degree of pulsation was noted as absent, +, ++, +++ and ++++. Oscillo-

less striking, especially in cases of interstitial cystitis where the lesions are not on the trigone. This brings up again the difference in the anatomical distribution of the nerves, as stated earlier, in such cases, excision of the superior hypogastric plexus is not sufficient to bring about relief of pain. We are now using radical excision of the pelvic sympathetics along with the intrathecal injection of alcohol in all cases of interstitial cystitis, but the series is not large enough nor the individual cases of long enough duration to permit the drawing of conclusions. The results are, however, very gratifying.

#### CONCLUSIONS

Sympathetic surgery for the relief of bladder pain in incurable tuberculous cystitis is a rational procedure.

The results of excision of the superior hypogastric plexus and lateral sacral chains show significant and lasting improvement, in contradistinction to cases with less complete denervation reported in the literature.

The intrathecal injection of alcohol, with controlled subarachnoid dispersion, in connection with surgery gives a complete sensory denervation, without incontinence.

The evidence from all sources points obviously to arteriosclerosis as the real menace threatening the diabetic patient, but why he should be more vulnerable to cardiovascular changes than a person without the disease is still unknown. However, investigators have for some time suspected that improper fat metabolism is of sufficient importance to merit thorough study, and there is ample evidence justifying that suspicion.

The thick and milky appearance of blood drawn from a patient with diabetes was a common observation when bloodletting was in vogue. Its significance, however, aroused very little comment, and was obviously lost sight of until Fischer<sup>8</sup> in 1903 made a similar observation. He concluded that the blood lipoids were elevated in diabetes. Bloor,<sup>9</sup> after studying a group of cases from Joslin's clinic, corroborated Fischer's contention. A similar study by Gray<sup>10</sup> on 171 patients revealed very high blood-fat values in 78 per cent of the cases, and after correlating the high-fat values with the duration of life in the fatal cases he concluded that they were of grave prognostic significance. Today, such a gloomy outlook is not justified because of the stabilizing effect of insulin on blood cholesterol.

Rabinowitch<sup>11</sup> believes that there is a definite relation between high blood-lipoid values and cardiovascular disease, especially among younger diabetic patients. His study revealed that those who showed evidence of cardiovascular damage invariably had high blood-cholesterol values. Re-

cently, Leary<sup>12</sup> confirmed the observations of earlier investigators.<sup>13, 14</sup> By feeding cholesterol to rabbits he succeeded in producing lesions simulating human atherosclerosis, and he regards this phenomenon as a specific disorder of the cholesterol metabolism.

Obviously, any study which deals with the etiology of arteriosclerosis should include blood-cholesterol determinations. It is interesting to contrast the blood-lipoid values as reported by investigators<sup>9, 10</sup> prior to the insulin era with those reported since the use of insulin and better diets.<sup>15, 16</sup> Already there are indications, or at least assumptions, that the incidence of arteriosclerosis is on the decline. Shepardson<sup>17</sup> believes that the reduced incidence parallels the reduction of lipemia since the advent of insulin therapy.

For the early diagnosis of arteriosclerosis, however, no one method is sufficient. The manifestations are varied and many. The detection of cardiovascular disease is best studied from various angles. A roentgenological study of the cardiovascular system is very helpful. Bowen and Koenig<sup>18</sup> have been able to demonstrate vascular changes in the lower extremities in 63 per cent of patients beyond the age of forty. In a similar study by Morrison and Bogan,<sup>19</sup> a total of 162 observations revealed the following interesting fact: the longer the duration of the diabetes the greater the incidence of arteriosclerosis. Forty per cent of those who had had diabetes for five years showed evidence of arteriosclerosis, and the percentages for the ten-, fifteen- and twenty-year groups were 50, 83 and 92 respectively.

For additional methods the reader is referred to papers by other authors. The procedures for studying the degree of vascular disease are, singly or in combination, the oscillometer, the response to a cutaneous injection of a diluted solution of histamine, palpation of the pulsations of the dorsalis pedis and posterior tibial arteries and examination of the fundi and retinal vessels.

In this report an attempt is made to evaluate the merits of the various tests and to ascertain the virtue of supplementing one with another. One hundred cases selected at random from the Diabetic Clinic at the Rhode Island Hospital were studied. Blood-sugar and blood-cholesterol determinations were made in each case. The extremities were x-rayed and the degree of calcification was noted. The fundi, especially the retinal vessels, were studied and for the sake of uniformity were all examined by the same physician, Dr. Harry C. Messinger. The pulsations of the dorsalis pedis and posterior tibial arteries were recorded and the degree of pulsation was noted as absent, +, ++, +++ and ++++. Oscillo-

metric tracings were taken and cutaneous histamine reactions observed in all suspected cases. The scheme adopted for the study of each case was as follows:

- 1 Name and age
- 2 Eyes
  - a Intraocular inflammation
  - b Cataract
  - c Eye muscles
  - d Fundi, especially retinal vessels
- 3 Duration of diabetes
  - a History
  - b Length of time in clinic
- 4 Blood pressure
- 5 Blood sugar
- 6 Blood cholesterol
- 7 Dorsalis pedis pulsation
  - a Right
  - b Left
- 8 Posterior tibial pulsation
  - a Right
  - b Left
- 9 X-ray study of lower extremities for evidence of arterial calcification
- 10 Oscillometric tracing on all cases showing either calcification by roentgenography or poor peripheral circulation by palpation, or both
- 11 Histamine cutaneous test in all cases showing pathologic changes in lower extremities

An analysis of this study, taking the group of cases as a whole, reveals a 38 per cent incidence of arteriosclerosis. However, when the cases are classed by decades of life one readily notes an increase in the incidence with each decade (Table 2). There are no cases in the first and second decades

entire group gave a systolic pressure reading higher than 150, and, interestingly enough, in no patient under thirty was the blood pressure above normal. However, 11 (28 per cent) of those showing evidence of sclerosis had hypertension.

Does an abnormal blood sugar forecast the early development of arteriosclerosis? In the opinion of Mosenthal,<sup>25</sup> hyperglycemia is in no way a causative factor, and this is confirmed by our study. Ninety-two per cent of the group gave blood-sugar readings greater than 120 mg per cent (the accepted normal), while of the patients with arteriosclerosis only 32 (85 per cent) had blood-sugar values higher than 120 mg.

Some observers<sup>11</sup> have stated that there is distinct relation between blood lipids and arteriosclerosis. The cholesterol studies in this group do not warrant such a conclusion. Only 23 per cent of the total cases, and only 8 (21 per cent) of the arteriosclerotic cases, gave readings higher than 225 mg per cent (the accepted normal). The discrepancy between the conclusions of other observers and the findings in this group may be attributed to our use of insulin, and to the change from a high-fat, low-carbohydrate diet to a low fat and high-carbohydrate one. Insulin seems to exert a stabilizing effect on fat metabolism. The cholesterol values have not been nearly so high since the use of insulin and of diets approaching normal.

Deposition of calcium in the vessel walls indicates vascular disease. Roentgenologically this

Table 2 Clinical and Laboratory Findings in Entire Group, Arranged by Decades

Decade	No. of Cases	Duration of Diabetes		Blood Pressure			Blood Sugar			Blood Cholesterol			Evidence of Arteriosclerosis	
		Average	Range	High	Low	Average	High	Low	Average	High	Low	Average	No	Per cent
		yr	yr	mm	mm	mm	mg	mg	mg	mg	mg	mg

Second	16	4.0	½ to 7	134/80	82/50	107/63	480	190	300.7	280	157	229.1	1	8
Third	12	5.7	½ to 14½	130/85	110/70	116/73	400	80	238	272	100	181.5	6	43
Fourth	12	5.5	½ to 12	180/105	100/80	119/79	334	112	203.7	286	94	206.25	2	17
Fifth	14	4.8	½ to 11	190/98	110/65	134/77	298	89	163.5	240	130	195	6	43
Sixth	23	3.4	½ to 12	200/120	110/70	142/83	364	121	190.5	300	133	197	11	48
Seventh	17	4	½ to 17	220/80	130/80	153/84	236	82	168	300	164	203.6	13	77
Eighth	5	9	5 to 14	180/108	100/80	164/79	200	115	152.4	200	182	194	5	100

In the third decade the incidence is 8 per cent, in the fourth 17 per cent, and so on until we reach the ninth decade, where the incidence is 100 per cent. It would be irrational to consider diabetes the sole offender in this climbing incidence. Undoubtedly a considerable portion of vascular disease can be and should be attributed to normal degenerative changes relevant to age.

The question of hypertension in diabetes and its relation to arteriosclerosis is also of interest. Are the two parallel? Only 18 per cent of this

can be demonstrated very adequately. X-ray studies of the lower extremities were made on all our patients. Twenty-four per cent of the entire group showed evidence of sclerosis as compared with 63 per cent in the arteriosclerotic group (Table 3). However, advanced sclerosis may exist without one's being able to demonstrate such deposition roentgenologically, as evidenced by the 14 cases with negative x-ray findings but with other indications of vascular damage.

The pulsations of the dorsalis pedis and pos-

terior tibial arteries are important objectives when searching for information regarding the circulation in the lower extremities. A good dorsalis pedis pulse was observed in 25 (66 per cent) of the arteriosclerotic group, the pulse was diminished in 6 cases and absent in 7. A good posterior tibial pulse was noted in 11 cases (29 per cent), the pulse was diminished in 6 cases and absent in 21. Does a good pulse rule out arteriosclerosis? Obviously not. Sixteen (66 per cent) of the 24 cases showing calcium deposition in the vessel walls by x-ray had either a good dorsalis pedis pulse or a good posterior tibial pulse, or both. Again, curiously enough, in 3 cases with no pulsation the roentgen-ray findings were negative.

In the study of the eyes no incidence of intraocular inflammation was noted and in only 1 patient was muscular abnormality found. The case report follows.

H.D., 46 years old, had had diabetes for 3 years. The blood pressure was 130/80, the blood sugar 118 mg per cent and the blood cholesterol 200 mg per cent. No

in the eighth. Twenty-three per cent of the entire group, or 60 per cent of the arteriosclerotic group, had retinal lesions. 1 in the third decade, 4 in the fifth, 6 in the sixth, 9 in the seventh and 5 in the eighth. Here, too, one is at a loss as to how much to blame the diabetes and how much the advancing age. Only 4 of the patients under fifty showed retinal changes, as compared with 19 of those aged fifty and over. These findings compare favorably with those of Spalding and Curtis,<sup>28</sup> who found a 20 per cent incidence of arteriosclerosis on ophthalmoscopic examination of the eye grounds.

The arteriosclerotic group was studied for possible detection of deficient circulation of the lower extremities with the oscillometer and the histamine intracutaneous test. The Pachon recording oscillometer was employed, and the readings at the ankle joint were recorded at various pressure levels. The height of the oscillations was used in grading the degree of efficiency of the circulation. With an oscillation of 5 mm or over the circulation was

calcification was shown by x-ray, and both the dorsalis pedis and posterior tibial pulsations were good.

The eye findings were as follows. The pupils are equal, regular and react to light and accommodation. The motility of the right eye is limited in all directions except outward and upward, the greatest limitation being inward. The eyes are prominent and the right fissure is slightly larger than the left. There seems to be a myasthenia of the extraocular muscles, most marked in the right eye and especially in the right internal rectus. There are no retinal changes.

This patient had a unilateral thyroidectomy 3 years prior to this study and his present basal metabolic rate is +34 per cent. He shows no evidence of arteriosclerosis.

Five patients showed evidence of cataract formation. 1 in the fifth decade, 3 in the seventh and 1

considered good or adequate, with 2 to 4 mm. as fair, with 1 mm. as poor, with no response as zero. Fifteen cases (39 per cent) showed normal oscillogram tracings, in 7 (18 per cent) the tracings were considered fair, 15 (39 per cent) gave a poor reading, and in 1 case the reading was zero.

How may one interpret with impunity the low incidence of circulatory impairment and the high incidence of relatively normal readings? Kramer<sup>20</sup> supplies a satisfactory answer when he says, "Since the mechanism of the oscillometer is so arranged as to give us information upon the gross blood flow and the rhythmic expansion and contraction of the vessels, it is only fair to assume that if a

satisfactory collateral circulation has been established we may get normal readings despite the presence of definite disease in some of the vessels." The presence of vascular damage does not necessarily imply that the circulation is not patent.

The histamine intracutaneous test was carried out on 34 of the arteriosclerotic patients. One tenth of one cubic centimeter of a 1:1000 solution was injected intracutaneously and the response was noted at five-, ten- and fifteen-minute intervals. The sites selected were those above and below the knee, above the ankle and on the dorsum of the foot. Normally a flare and a wheal appear at the end of five minutes and usually become more marked at the time of the ten-minute observation. At the end of fifteen minutes, if no local reaction is observed the response is considered negative. In 23 cases (67 per cent) the reaction was normal. Six (17 per cent) showed a delayed response. In 4 (12 per cent) the reaction was minimal and in 2 (6 per cent) it was absent. All the patients except 2 who showed a normal response to histamine had a normal (good) oscillometric tracing. Here again the high incidence of a normal response does not discredit the test. On the contrary, the test gives one information as to the patency of the capillaries and peripheral circulation and indirectly tells one something about the status of the deep and large vessels.

Table 3 summarizes the positive findings in the arteriosclerotic group. It will be observed that by a combination of methods the incidence is 38 per cent. It is also of interest to note that the number of cases which showed hypertension parallels fairly well the numbers which showed positive x-ray findings and retinal arteriosclerosis—18, 24 and 23 per cent respectively. A good pulsation means an efficient circulation, but by no means indicates absence of vascular disease. However, when no pulse is present and in addition one gets a negative oscillometer reading and a poor histamine response, it is safe to assume that vascular lesions are present and that the circulation is impaired. Interestingly enough, the 13 patients with poor or no pulsation of the dorsalis pedis artery compare favorably with the 16 who showed a poor oscillometric index. The histamine response was negative or poor in 6 cases. The pulse of the posterior tibial artery was at least only poorly palpated in 27, in only 8 were the lipid values above normal, while high blood-sugar values were found in 32.

#### CONCLUSIONS

A multiplicity of methods yields a far greater incidence of arteriosclerosis than does any one single method.

The blood-cholesterol values have decreased to a relatively normal level since the advent of insulin and the use of diets containing a high-carbohydrate and low-fat content.

The number of patients having a poor or no pulsation of the peripheral vessels of the lower extremities compares favorably with the number showing a poor oscillometric index.

The histamine intracutaneous response is the most reliable guide in determining the presence or absence of a sufficient collateral circulation.

The ophthalmological examination of the fundi, the x-ray study of the lower extremities and the blood-pressure readings demonstrate a relatively equal incidence of arteriosclerosis.

# ALCOHOL TOLERANCE TESTS IN NORMAL INDIVIDUALS AND IN PATIENTS WITH DIABETES MELLITUS AND DIABETES INSIPIDUS\*

The Effect of Pituitrin, Insulin, Food and Forced Water on Blood and Urine Alcohol Levels After The Ingestion of Alcohol

HARRY BLOTNER, M.D.†

BOSTON

ALCOHOL is absorbed with extreme rapidity from the gastrointestinal tract, even though it destroys digestive enzymes<sup>1</sup> and prevents or delays the proper digestion of food.<sup>2</sup> Furthermore, Mellanby<sup>3</sup> and others have shown that the metabolism of alcohol, regardless of the amount present, proceeds at a constant rate for the individual. There are very few conditions which are known to modify the rate of absorption or metabolism of alcohol. For example, insulin has been said by some to increase the rate of disappearance of alcohol from the blood, whereas food was thought to slow the rate of its absorption.

Normal people have a varying tolerance to alcohol, just as they do to tobacco and other drugs. A few patients with diabetes insipidus have told me that they can tolerate liquor better than normal people. Frequently patients with diabetes mellitus ask whether a drink of alcohol would do them harm. To investigate these points appeared to be of practical importance.

This paper presents a study of alcohol tolerance tests in normal and diabetic persons, and of the effect of pituitrin, insulin, food and forced water intake on these tests.

## METHODS

The alcohol tolerance was determined in much the same way that glucose tolerance is ordinarily studied. A dose of 0.6 cc. of absolute alcohol per kilogram of body weight was employed as a test meal. The standard solution contained 50 cc absolute alcohol, 50 cc. grapejuice and 150 cc water. This was a reasonably palatable mixture and never caused vomiting, nausea or diarrhea. It was chilled and administered to the patients in the morning after fasting overnight. The alcohol concentration was determined in simultaneous samples of venous blood and urine which were obtained before the test meal and at half-hour intervals for four hours thereafter. The dose of absolute alcohol usually varied from 40 to 50 cc. The patients remained in the laboratory during the test period without additional food, but with

some added water if desired. The symptoms of intoxication were noted.

The chemical method at first used for the determination of alcohol was that described by Fleming and Stotz.<sup>4</sup> It is a modification of that employed by Nicloux<sup>5</sup> for use of the Folin-Wu blood filtrate, and is based on the principle of the reduction of potassium dichromate in sulfuric acid, with the estimation of the excess by ferrous ammonium sulfate and titration with potassium permanganate. Chiefly because the potassium permanganate solution is unstable, and because to adjust it to proper strength often requires considerable time, the method was modified further in this clinic<sup>6</sup> to determine the concentration of alcohol by the Evelyn photoelectric colorimeter.<sup>7</sup> This measures directly the diminution of the color of the acid bichromate solution due to reduction by alcohol, and eliminates the potassium permanganate and ferrous ammonium sulfate solutions and the titration. The results obtained are accurate and agree with those obtained with the titration method.<sup>6,8</sup>

The analyses were made on 10 cc. of the Folin-Wu blood filtrate and on 10 cc and 1 cc of the urine obtained before and after alcohol ingestion respectively.

## ALCOHOL TOLERANCE CURVES IN NORMAL PEOPLE

The alcohol tolerance was studied, first, in 10 normal persons in order to obtain a standard with which to compare the tolerances observed in diabetic patients. The average urine and blood values are given in Chart 1. The fasting blood alcohol varied from 0 to 7 mg per cent. After the ingestion of alcohol there was a rise in the curve, which reached its average maximum concentration of 41 mg in one hour and decreased gradually to a level of approximately 15 mg in four hours.

The fasting urine alcohol varied from 0.4 to 2 mg per cent. After the ingestion of alcohol it rose to an average maximum concentration of 50 mg in one and a half hours, and decreased in four hours to an average level of 16 mg. This concentration was appreciably lower than that in the blood at the first half hour, but exceeded it at

\*From the Medical Clinic of the Peter Bent Brigham Hospital, Boston.  
†Associate in medicine, Peter Bent Brigham Hospital, Boston.

one hour and one and a half hours. Also the blood alcohol, during its period of decline, was slightly lower than the urine alcohol. Smith and Stewart<sup>9</sup> surmised that this relation between blood and urine alcohol was to be expected.

It was interesting to observe that some symptoms of intoxication appeared in these individuals, in spite of the fact that the blood-alcohol concentrations were less than 63 mg per cent. These symptoms included being exhilarated, euphoric, talkative, slightly dizzy and unstable. The findings were in striking contrast to those observed by Selesnick,<sup>10</sup> who noted that the clinical manifestations of intoxication did not appear in alcoholic patients at the Boston City Hospital until the blood

2 patients the tests were repeated two and three times, with similar findings.

The alcohol curves obtained in diabetes insipidus without pituitrin therapy were similar to those observed in normal persons. There was, however, a slightly sharper rise with a slightly greater maximum level and a slightly sharper drop in these alcohol curves than in those of normal persons. Four hours after the alcohol meal the concentrations were approximately the same as normal.

With pituitrin therapy, the first half of the alcohol curve was definitely lower in diabetes insipidus than without this drug (Chart 2). In addition, pituitrin caused the alcohol concentration in the urine to rise less than that in the blood

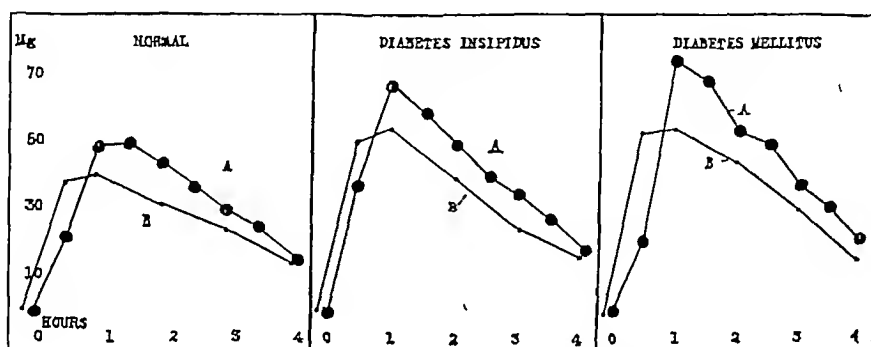

Chart 1 Response to Ingestion of Alcohol

*Average curves for urine (A) and blood (B) alcoholic contents obtained in 10 normal people, 5 with diabetes insipidus and 6 with diabetes mellitus, after the ingestion of 0.6 cc of absolute alcohol per kilogram of body weight. In this and subsequent charts the alcohol is recorded in milligrams per cent.*

alcohol exceeded 200 mg per cent. It is quite likely that this marked difference is due to the fact that Selesnick's patients were chronic alcoholics who could tolerate a much higher blood alcohol level through habituation than could normal persons. On the other hand, Heise<sup>11</sup> found that loss of efficiency and impairment of judgment occurred even when the blood and urine contained as little as 20 mg per cent of alcohol.

#### ALCOHOL TOLERANCE IN DIABETES INSIPIDUS, WITH AND WITHOUT PITUITRIN THERAPY

Alcohol tolerance tests were obtained in 5 patients with diabetes insipidus after pituitrin had been omitted for a few days and the fluid intake and output had been markedly increased (Chart 1). The tests were repeated after the patients had received pituitrin for several days, when the fluid intake and output were normal. The morning of the day of this test, 1 cc of obstetrical pituitrin was administered intranasally on a pledget of cotton immediately after the imbibing of alcohol. In

within half an hour after the alcohol meal, and to a slighter degree within one hour after it. The second half of the curve was much the same as without the administration of pituitrin.

Pituitrin appeared to prevent the usual rise in the alcohol concentration in the blood and urine after the alcohol meal. This may be due to the pituitrin's having inhibited the absorption of alcohol, or to the fact that in uncontrolled diabetes insipidus the alcohol is not metabolized so quickly as in the controlled disease.

It was noted that the blood and urine alcohol levels were higher when the alcohol was taken without pituitrin than with pituitrin. After the administration of pituitrin each specimen of urine usually amounted to only 10 or 20 cc, whereas without pituitrin the volume was as high as 400 cc. This indicates that the kidneys acted as an inert membrane and that the alcohol passed through them into the urine by simple diffusion, as suggested by Ambard,<sup>12</sup> Widmark<sup>13</sup> and others. Con-

sequently the largeness of the volume of urine did not dilute its alcohol content.

It was of unusual significance that the toxic effect of alcohol was more marked and more prolonged with pituitrin therapy, even though the blood and urine alcohol levels were lower. The toxic symptoms increased so much that pituitrin administered with the alcohol put 3 of the patients to sleep, 1 patient, however, showed no special

tests were compared with those of the controls who received no Pitressin or extra water.

The increased water intake produced a slightly greater concentration of alcohol in the blood and urine during the first one and a half hours after the ingestion of alcohol than occurred during the control test (Chart 3). It was interesting that the alcohol concentrations were not diluted, although the volume of urine was increased more than tenfold at times. Miles<sup>14</sup> also found that changes in the amount of urine per minute did not influence significantly the alcohol concentration in the urine. In contrast, Pitressin perceptibly decreased the volume of urine and the alcohol concentration in the blood and urine at two hours after alcohol ingestion as it did in diabetes insipidus. Widmark,<sup>15</sup> on the other hand, found that pituitrin did not alter the blood alcohol curves in dogs.

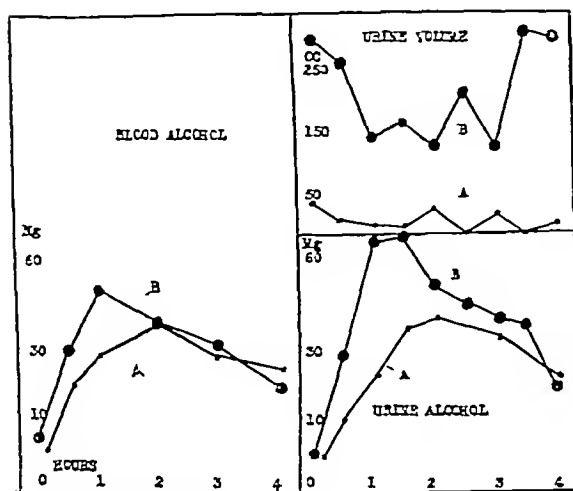

Chart 2. Blood and Urine Findings in a Case of Diabetes Insipidus

*Simultaneous curves showing the blood and urine alcoholic contents and the urine volume in a man with diabetes insipidus after the ingestion of 35 cc of absolute alcohol with (A) and without (B) pituitrin therapy.*

change. All the patients seemed to experience a more immediate effect of the alcohol without pituitrin.

The interpretation of these results is controversial, as is the whole problem of alcohol tolerance. However, pituitrin possibly caused the retention of a greater amount of alcohol in the tissues, giving intensified alcoholic symptoms. Under such circumstances the blood and urine alcohol might not give a proper indication of the alcohol concentration in those tissues.

#### FORCED WATER INTAKE AND ALCOHOL TOLERANCE

An attempt was made to produce a condition similar to diabetes insipidus in 5 normal persons by having them drink large amounts of water during the test period, so that they voided large volumes of urine. Four or five days later the tests were repeated with 1 cc of Pitressin being given intranasally, when the usual dose of alcohol was ingested and the urine output was small. These

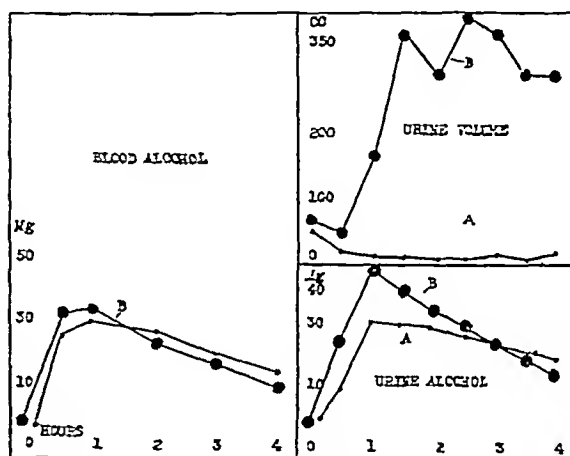

Chart 3. Blood and Urine Findings in a Normal Man

*Simultaneous curves showing the blood and urine alcoholic contents and the urine volume in a normal man after the ingestion of 50 cc of absolute alcohol with pituitrin administration (A) on one day, and the forcing of water (B) on another.*

The alcoholic symptoms appeared a little sooner with the forced water intake than was the case during the control tests, although the duration was about the same. In 2 persons the added water caused slightly fewer toxic symptoms and in 2 individuals slightly more. In 3 normal persons who received Pitressin administered with alcohol, the symptoms were less marked in 1 than during the control test, about the same in 1, and more pronounced in 1.

It appears from the laboratory results that forcing water might be of value in the treatment of alcoholism in increasing the elimination of alcohol, although symptomatically there was no significant change. In terms of milligrams, the amount of alcohol eliminated in the urine in cer-

one hour and one and a half hours. Also the blood alcohol, during its period of decline, was slightly lower than the urine alcohol. Smith and Stewart<sup>9</sup> surmised that this relation between blood and urine alcohol was to be expected.

It was interesting to observe that some symptoms of intoxication appeared in these individuals, in spite of the fact that the blood-alcohol concentrations were less than 63 mg per cent. These symptoms included being exhilarated, euphoric, talkative, slightly dizzy and unstable. The findings were in striking contrast to those observed by Selesnick,<sup>10</sup> who noted that the clinical manifestations of intoxication did not appear in alcoholic patients at the Boston City Hospital until the blood

2 patients the tests were repeated two and three times, with similar findings.

The alcohol curves obtained in diabetes insipidus without pituitrin therapy were similar to those observed in normal persons. There was, however, a slightly sharper rise with a slightly greater maximum level and a slightly sharper drop in these alcohol curves than in those of normal persons. Four hours after the alcohol meal the concentrations were approximately the same as normal.

With pituitrin therapy, the first half of the alcohol curve was definitely lower in diabetes insipidus than without this drug (Chart 2). In addition, pituitrin caused the alcohol concentration in the urine to rise less than that in the blood

alcohol exceeded 200 mg per cent. It is quite likely that this marked difference is due to the fact that Selesnick's patients were chronic alcoholics who could tolerate a much higher blood alcohol level through habituation than could normal persons. On the other hand, Heise<sup>11</sup> found that loss of efficiency and impairment of judgment occurred even when the blood and urine contained as little as 20 mg per cent of alcohol.

#### ALCOHOL TOLERANCE IN DIABETES INSIPIDUS, WITH AND WITHOUT PITUITRIN THERAPY

Alcohol tolerance tests were obtained in 5 patients with diabetes insipidus after pituitrin had been omitted for a few days and the fluid intake and output had been markedly increased (Chart 1). The tests were repeated after the patients had received pituitrin for several days, when the fluid intake and output were normal. The morning of the day of this test, 1 cc of obstetrical pituitrin was administered intranasally on a pledget of cotton immediately after the imbibing of alcohol. In

within half an hour after the alcohol meal, and to a slighter degree within one hour after it. The second half of the curve was much the same as without the administration of pituitrin.

Pituitrin appeared to prevent the usual rise in the alcohol concentration in the blood and urine after the alcohol meal. This may be due to the pituitrin's having inhibited the absorption of alcohol, or to the fact that in uncontrolled diabetes insipidus the alcohol is not metabolized so quickly as in the controlled disease.

It was noted that the blood and urine alcohol levels were higher when the alcohol was taken without pituitrin than with pituitrin. After the administration of pituitrin each specimen of urine usually amounted to only 10 or 20 cc., whereas without pituitrin the volume was as high as 400 cc. This indicates that the kidneys acted as an inert membrane and that the alcohol passed through them into the urine by simple diffusion, as suggested by Ambard,<sup>12</sup> Widmark<sup>13</sup> and others. Con-

sequently the largeness of the volume of urine did not dilute its alcohol content

It was of unusual significance that the toxic effect of alcohol was more marked and more prolonged with pituitrin therapy, even though the blood and urine alcohol levels were lower. The toxic symptoms increased so much that pituitrin administered with the alcohol put 3 of the patients to sleep, 1 patient, however, showed no special

change. All the patients seemed to experience a more immediate effect of the alcohol without pituitrin.

The interpretation of these results is controversial, as is the whole problem of alcohol tolerance. However, pituitrin possibly caused the retention of a greater amount of alcohol in the tissues, giving intensified alcoholic symptoms. Under such circumstances the blood and urine alcohol might not give a proper indication of the alcohol concentration in those tissues.

#### FORCED WATER INTAKE AND ALCOHOL TOLERANCE

An attempt was made to produce a condition similar to diabetes insipidus in 5 normal persons by having them drink large amounts of water during the test period, so that they voided large volumes of urine. Four or five days later the tests were repeated with 1 cc of Pitressin being given intranasally, when the usual dose of alcohol was ingested and the urine output was small. These

tests were compared with those of the controls who received no Pitressin or extra water.

The increased water intake produced a slightly greater concentration of alcohol in the blood and urine during the first one and a half hours after the ingestion of alcohol than occurred during the control test (Chart 3). It was interesting that the alcohol concentrations were not diluted, although the volume of urine was increased more than ten-fold at times. Miles<sup>14</sup> also found that changes in the amount of urine per minute did not influence significantly the alcohol concentration in the urine. In contrast, Pitressin perceptibly decreased the volume of urine and the alcohol concentration in the blood and urine at two hours after alcohol ingestion as it did in diabetes insipidus. Widmark,<sup>15</sup> on the other hand, found that pituitrin did not alter the blood alcohol curves in dogs.

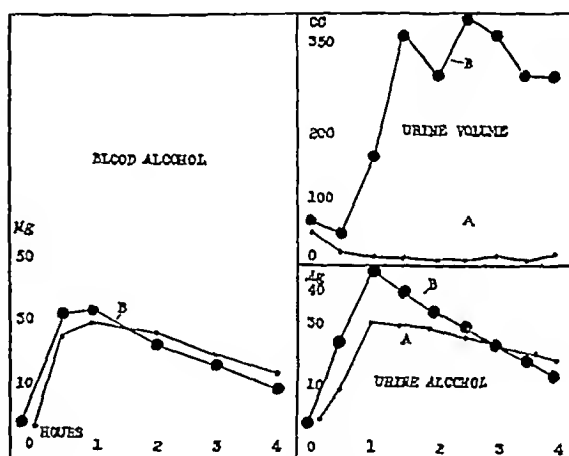

Chart 3 Blood and Urine Findings in a Normal Man

*Simultaneous curves showing the blood and urine alcoholic contents and the urine volume in a normal man after the ingestion of 50 cc of absolute alcohol with pituitrin administration (A) on one day and the forcing of water (B) on another*

The alcoholic symptoms appeared a little sooner with the forced water intake than was the case during the control tests, although the duration was about the same. In 2 persons the added water caused slightly fewer toxic symptoms and in 2 individuals slightly more. In 3 normal persons who received Pitressin administered with alcohol, the symptoms were less marked in 1 than during the control test, about the same in 1, and more pronounced in 1.

It appears from the laboratory results that forcing water might be of value in the treatment of alcoholism in increasing the elimination of alcohol, although symptomatically there was no significant change. In terms of milligrams, the amount of alcohol eliminated in the urine in cer

tain cases after drinking alcohol and extra water was considerably increased. However, this was not of practical value since the normal individual, without forcing water, excreted in the urine 0.1 to 0.9 per cent of the ingested alcohol in four hours, compared with 1.6 to 3.4 per cent when the water intake was forced, and the amount of urine varied from 1570 to 3495 cc. Furthermore, in the marked diuresis in untreated diabetes insipidus 1.4 to 3.2 per cent of the alcohol was eliminated in the urine during the test period, compared with 0.07 to 0.22 per cent when the disease was controlled with pituitrin and the urine output was practically normal. Forcing large amounts of water only increased the excretion of alcohol in the urine to approximately 1 to 3 per cent.

#### ALCOHOL TOLERANCE IN DIABETES MELLITUS, WITH AND WITHOUT INSULIN THERAPY

The consideration of the immediate effect of alcohol on the blood and urine alcohol concentra-

viduals (Chart 1). However, the important finding was that the maximum alcohol concentration of the blood and urine about one hour after the alcohol meal was appreciably higher in the diabetic patients, although the fasting blood and urine alcohol concentrations were normal. The cause for this is conjectural. The greater rise may be due to an increased rate of absorption of alcohol. Possibly diabetic patients cannot metabolize the alcohol as rapidly as normal persons, so that there is a greater accumulation of alcohol in the blood and greater concentration in the urine. Incidentally, there was some decrease in the blood sugar level during the test period.

Haggard and Greenberg<sup>16</sup> found that increasing the blood sugar in rats greatly lessened the pharmacological effect of alcohol that had been absorbed. If this were true clinically, certain diabetic patients would have an increased tolerance to alcohol. However, the toxic effect of alcohol was much the same in the diabetic patients as in the normal persons, although 2 of the former ex-

tion and its toxicity in patients with diabetes mellitus is an important and practical problem.

The alcohol-tolerance curves were determined in 6 patients with diabetes mellitus and compared with those obtained in normal people. The blood and urine also were examined for sugar. There was no acetone or diacetic acid in the urine specimens.

There was a similar relation between the blood and urine alcohol levels in the diabetic patients without insulin therapy as in the normal indi-

viduals experienced considerable staggering after the alcohol meal.

There have been several reports<sup>17-21</sup> suggesting that insulin causes an increase in the rate of disappearance of alcohol from the blood. It seemed to us that if this were correct, it could be proved in diabetic patients in whom the blood sugar could be changed with insulin from a high to a low level in a short period of time. Consequently, the alcohol-tolerance tests were repeated in these patients after an interval of several

days, when 10 to 25 units of insulin were injected subcutaneously immediately before the alcohol was ingested (Table 1)

It was observed that insulin did not alter the blood and urine alcohol curves, despite the marked drop in the blood sugar to a hypoglycemic level during the test period (Chart 4) In fact,

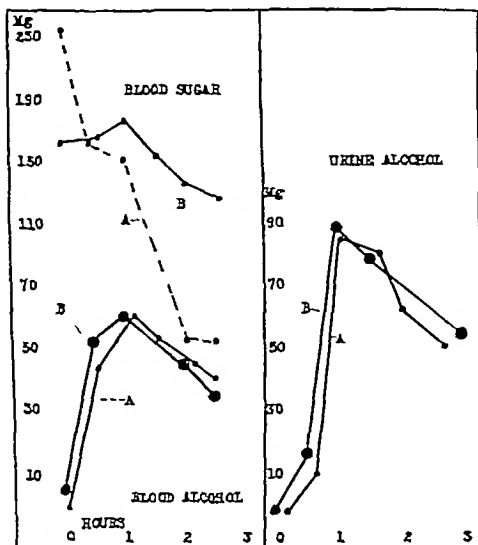

Chart 4 Blood and Urine Findings in a Case of Diabetes Mellitus

*Simultaneous curves showing the blood and urine alcoholic contents and the urine volume in a man with diabetes mellitus after the ingestion of 40 cc of absolute alcohol with (A) and without (B) the injection of 20 units of insulin*

the curves were practically identical with the control tests. It was obvious from these experiments that insulin does not affect alcohol metabolism in diabetes mellitus. Furthermore, it produced no change in the toxic symptoms caused by the alcohol. Nevertheless, during hypoglycemia a toxicity appeared which was no doubt due to the hypoglycemia and not to the alcoholemia. In addition, 0.4 to 1.0 per cent of the ingested alcohol was excreted in the urine in four hours, and this amount was not appreciably affected by the injection of insulin.

A few investigators have observed that insulin increased the rate with which alcohol disappeared from the body. Supniewski<sup>17</sup> showed that the subcutaneous administration of insulin into normal animals at the same time as alcohol was given caused the blood alcohol to be reduced. Aoki<sup>18</sup> noted a hypoalcoholemia in fowls ninety minutes after the injection of insulin. Widmark<sup>15</sup> found that insulin increased the rate of disappearance of alcohol in dogs as much as 200 per cent. Newman and Cuttng<sup>19</sup> obtained a 50 per cent in-

crease in alcohol metabolism with therapeutic doses of insulin in human subjects. Schlichting<sup>20</sup> also observed that insulin hastened alcohol metabolism. From experiments made on subjects with normal blood sugar, Bickel<sup>21</sup> concluded that insulin was effective in accelerating the speed of alcohol metabolism by lowering the blood sugar, and that when this was prevented by ingestion of sugar no increase in rate occurred.

In contrast, there is good evidence that insulin has no effect on alcohol metabolism. Hirschfelder and Maxwell<sup>22</sup> determined that insulin did not increase the oxidation of alcohol in the body or antagonize its toxic effect. Dell'Acqua,<sup>23</sup> as well as Lang and von Schlick,<sup>24</sup> could perceive no effect of insulin on alcoholemia. Fleming and Reynolds<sup>25</sup> found that the injection of insulin into human beings did not modify the concentration of alcohol in the blood after the intravenous administration of alcohol. Siegmund and Flohr<sup>26</sup> obtained no evidence in 3 healthy men that medication with insulin reduced the symptoms or hastened the disappearance of the signs of intoxication. These findings agree with my results obtained in the patients with diabetes.

#### FOOD AND ALCOHOL TOLERANCE

It has long been known that food in the stomach has an inhibitory effect on the symptoms of alcohol intoxication. This has been attributed to the influence of food in decreasing the absorption of alcohol from the stomach into the blood stream.

This problem was studied in 4 patients with diabetes mellitus, in addition to the experiments on the effect of alcohol with and without the administration of insulin. In these tests the patients took a normal-sized breakfast. Approximately one hour later they received the standard dose of alcohol. In 2 cases insulin was injected just before the alcohol intake. The results were very striking (Chart 5). It is clear that the maximum concentrations of alcohol in the blood and urine after the ingestion of food and alcohol were much lower than they were when food was omitted. The addition of insulin injection to food made no great difference in the results.

An important observation was that the alcoholic symptoms following the ingestion of food were greatly decreased and hardly noticeable. Incidentally, similar results were obtained in patients with diabetes insipidus.

Just how food taken with alcohol causes a lowering of blood and urine alcohol levels is a controversial question. The action may be explained by a decreased rate of absorption of alcohol, as suggested by Mellanby.<sup>27</sup> If this were

tain cases after drinking alcohol and extra water was considerably increased. However, this was not of practical value since the normal individual, without forcing water, excreted in the urine 0.1 to 0.9 per cent of the ingested alcohol in four hours, compared with 16 to 34 per cent when the water intake was forced, and the amount of urine varied from 1570 to 3495 cc. Furthermore, in the marked diuresis in untreated diabetes insipidus 14 to 32 per cent of the alcohol was eliminated in the urine during the test period, compared with 0.07 to 0.22 per cent when the disease was controlled with pituitrin and the urine output was practically normal. Forcing large amounts of water only increased the excretion of alcohol in the urine to approximately 1 to 3 per cent.

ALCOHOL TOLERANCE IN DIABETES MELLITUS,  
WITH AND WITHOUT INSULIN THERAPY

The consideration of the immediate effect of alcohol on the blood and urine alcohol concentra-

viduals (Chart 1). However, the important finding was that the maximum alcohol concentration of the blood and urine about one hour after the alcohol meal was appreciably higher in the diabetic patients, although the fasting blood and urine alcohol concentrations were normal. The cause for this is conjectural. The greater rise may be due to an increased rate of absorption of alcohol. Possibly diabetic patients cannot metabolize the alcohol as rapidly as normal persons, so that there is a greater accumulation of alcohol in the blood and greater concentration in the urine. Incidentally, there was some decrease in the blood sugar level during the test period.

Haggard and Greenberg<sup>16</sup> found that increasing the blood sugar in rats greatly lessened the pharmacological effect of alcohol that had been absorbed. If this were true clinically, certain diabetic patients would have an increased tolerance to alcohol. However, the toxic effect of alcohol was much the same in the diabetic patients as in the normal persons, although 2 of the former ex-

#### FOOD AND ALCOHOL TOLERANCE

It has long been known that food in the stomach has an inhibitory effect on the symptoms of alcohol intoxication. This has been attributed to the influence of food in decreasing the absorption of alcohol from the stomach into the blood stream.

This problem was studied in 4 patients with diabetes mellitus, in addition to the experiments on the effect of alcohol with and without the administration of insulin. In these tests the patients took a normal-sized breakfast. Approximately one hour later they received the standard dose of alcohol. In 2 cases insulin was injected just before the alcohol intake. The results were very striking (Chart 5). It is clear that the maximum concentrations of alcohol in the blood and urine after the ingestion of food and alcohol were much lower than they were when food was omitted. The addition of insulin injection to food made no great difference in the results.

An important observation was that the alcoholic symptoms following the ingestion of food were greatly decreased and hardly noticeable. Incidentally, similar results were obtained in patients with diabetes insipidus.

Just how food taken with alcohol causes a lowering of blood and urine alcohol levels is a controversial question. The action may be explained by a decreased rate of absorption of alcohol, as suggested by Mellanby.<sup>27</sup> If this were

the case, the alcohol would disappear more slowly and remain in the body longer when food was taken. However, Carpenter and Lee<sup>28</sup> found that this was not the case. They examined the alcohol in expired air after the ingestion of alcohol and glucose, and found that it disappeared more rapidly than when no glucose was given. This raises the question whether the disappearance of alcohol is due to its combustion or to its transformation into some other substance. Southgate<sup>29</sup> ascribed this phenomenon not to delayed absorption but to the fact that a considerable fraction of the ingested alcohol is never manifested in the blood. This indicates that it is due to some chemical reaction. On the other hand, the experiments of Fleming

were increased in the former. This suggests that pituitrin causes greater retention of alcohol in the tissues of these patients than is indicated by the concentrations of blood and urine alcohol.

The appearance of an increase in the blood and urine alcohol levels following the ingestion of alcohol in patients with diabetes mellitus indicates that there is an increased rate of absorption of the drug in this disease, or that the alcohol cannot be metabolized as quickly as in normal cases. Even insulin had no effect on the blood and urine alcohol levels or on the symptoms of alcohol intoxication in diabetes mellitus.

No evidence was supplied that alcohol is more harmful to the diabetic patient than to the normal person, since the toxic effect of alcohol was much the same in both, although the alcohol curves were appreciably higher in the former. However, alcohol should not be recommended for the diabetic patient, because an alcoholic odor in his breath may lead to confusion in the diagnosis of coma due to insulin or acidosis.

It was interesting that food caused a decrease in the concentrations of blood and urine alcohol and also in the toxic symptoms following the ingestion of alcohol. Although this has been attributed to a physical action whereby the rate of alcohol absorption is decreased, there is other evidence which suggests that the cause may be a chemical reaction in which the metabolism of alcohol is increased.

The general relation between the concentrations of blood and urine alcohol appears to be that during the period of alcohol absorption its concentration in the blood is higher than that in the urine. One hour after the ingestion of alcohol the alcohol level of the urine was slightly higher than that of the blood and remained so during the period of alcohol decline. Nevertheless, the two levels were very close, even though large amounts of urine were voided. This suggests that alcohol passes through the kidneys into the urine by a simple process of diffusion. The reason for this slight difference has been explained<sup>32</sup> by the alcohol level's being slightly higher in arterial than in venous blood, and consequently giving the slight variation between the alcohol concentrations of the urine and of venous blood.

#### SUMMARY

This paper presents a study on some alcohol tolerance tests in normal persons and in patients with diabetes insipidus and diabetes mellitus following the ingestion of 0.6 cc of absolute alcohol per kilogram of body weight. The influences of insulin,

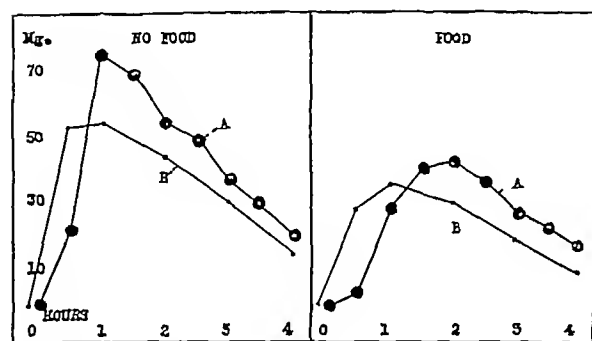

Chart 5 Response to Ingestion of Alcohol in Relation to Food

*Average curves for urine (A) and blood (B) alcoholic contents obtained in 4 patients with diabetes mellitus after the ingestion of 0.6 cc of absolute alcohol per kilogram of body weight, with and without the intake of food*

and Reynolds<sup>25</sup> suggested that certain foods do not affect alcohol metabolism. They gave egg albumin, milk, cream and olive oil after the intravenous injection of alcohol and found no significant change in the rate of disappearance of alcohol from the blood.

#### DISCUSSION

The study of alcohol tolerance is a fascinating one, although somewhat perplexing. The proper explanation of the results obtained in this investigation is at present uncertain because our knowledge of the intermediary metabolism and certain aspects of the utilization of alcohol in the body is incomplete. Insulin and pituitrin have been shown to have antagonistic effects on carbohydrate<sup>30</sup> and fat metabolism<sup>31</sup>. The data here reported suggest that the two substances do not influence alcohol metabolism in opposite ways. Pituitrin decreased the blood and urine alcohol levels in patients with diabetes insipidus and in normal individuals, but in spite of this the symptoms of alcoholic intoxica-

pituitrin, food and forced water intake on these tests were determined

Symptoms of alcoholic intoxication appeared in these people when the blood and urine alcohol concentrations were below 63 mg per cent, in comparison to much higher levels reported by others

The blood and urine alcohol curves after the test meal were very slightly higher in patients with diabetes insipidus than in normal persons. Pituitrin reduced the blood and urine alcohol levels in both these groups, yet notwithstanding this it increased considerably the symptoms of alcoholic intoxication in the former

In the patients with diabetes mellitus the blood and urine alcohol levels after the ingestion of alcohol were appreciably higher than normal, although the symptoms of alcoholic intoxication were much the same. The administration of insulin had no effect on the alcohol curves or on the symptoms of alcoholic intoxication. It appears that alcohol is no more harmful to the diabetic patient than to the normal individual, although an alcoholic odor on the breath may cause confusion in the diagnosis of coma due to insulin or acidosis

The ingestion of food before the ingestion of alcohol produced a striking decrease in the blood and urine alcohol levels and in the symptoms of alcohol intoxication in diabetic patients

The diuresis resulting from forced water intake and uncontrolled diabetes insipidus did not dilute the concentration of alcohol in the urine, but increased the total amount of alcohol excreted therein. Nevertheless, forcing water in the case of an alcoholic patient would not produce any appreciable results in therapy, because the total alcohol eliminated by this method is small compared to the amount of alcohol ingested

the case, the alcohol would disappear more slowly and remain in the body longer when food was taken. However, Carpenter and Lee<sup>28</sup> found that this was not the case. They examined the alcohol in expired air after the ingestion of alcohol and glucose, and found that it disappeared more rapidly than when no glucose was given. This raises the question whether the disappearance of alcohol is due to its combustion or to its transformation into some other substance. Southgate<sup>29</sup> ascribed this phenomenon not to delayed absorption but to the fact that a considerable fraction of the ingested alcohol is never manifested in the blood. This indicates that it is due to some chemical reaction. On the other hand, the experiments of Fleming

were increased in the former. This suggests that pituitrin causes greater retention of alcohol in the tissues of these patients than is indicated by the concentrations of blood and urine alcohol.

The appearance of an increase in the blood and urine alcohol levels following the ingestion of alcohol in patients with diabetes mellitus indicates that there is an increased rate of absorption of the drug in this disease, or that the alcohol cannot be metabolized as quickly as in normal cases. Even insulin had no effect on the blood and urine alcohol levels or on the symptoms of alcohol intoxication in diabetes mellitus.

No evidence was supplied that alcohol is more harmful to the diabetic patient than to the normal person, since the toxic effect of alcohol was much the same in both, although the alcohol curves were appreciably higher in the former. However, alcohol should not be recommended for the diabetic patient, because an alcoholic odor in his breath may lead to confusion in the diagnosis of coma due to insulin or acidosis.

It was interesting that food caused a decrease in the concentrations of blood and urine alcohol and also in the toxic symptoms following the ingestion of alcohol. Although this has been attributed to a physical action whereby the rate of alcohol absorption is decreased, there is other evidence which suggests that the cause may be a chemical reaction in which the metabolism of alcohol is increased.

The general relation between the concentrations of blood and urine alcohol appears to be that during the period of alcohol absorption its concentration in the blood is higher than that in the urine. One hour after the ingestion of alcohol the alcohol level of the urine was slightly higher than that of the blood and remained so during the period of alcohol decline. Nevertheless, the two levels were very close, even though large amounts of urine were voided. This suggests that alcohol passes through the kidneys into the urine by a simple process of diffusion. The reason for this slight difference has been explained<sup>32</sup> by the alcohol level's being slightly higher in arterial than in venous blood, and consequently giving the slight variation between the alcohol concentrations of the urine and of venous blood.

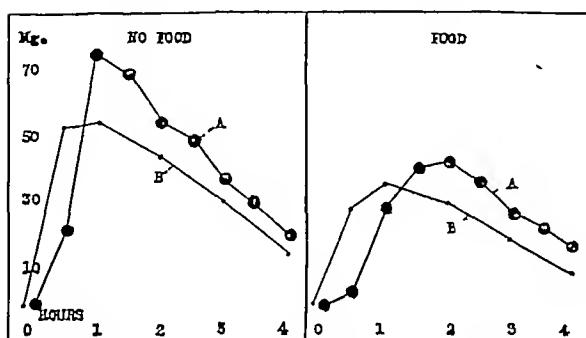

Chart 5 Response to Ingestion of Alcohol in Relation to Food

*Average curves for urine (A) and blood (B) alcoholic contents obtained in 4 patients with diabetes mellitus after the ingestion of 0.6 cc of absolute alcohol per kilogram of body weight, with and without the intake of food*

and Reynolds<sup>25</sup> suggested that certain foods do not affect alcohol metabolism. They gave egg albumin, milk, cream and olive oil after the intravenous injection of alcohol and found no significant change in the rate of disappearance of alcohol from the blood.

#### DISCUSSION

The study of alcohol tolerance is a fascinating one, although somewhat perplexing. The proper explanation of the results obtained in this investigation is at present uncertain because our knowledge of the intermediary metabolism and certain aspects of the utilization of alcohol in the body is incomplete. Insulin and pituitrin have been shown to have antagonistic effects on carbohydrate<sup>30</sup> and fat metabolism<sup>31</sup>. The data here reported suggest that the two substances do not influence alcohol metabolism in opposite ways. Pituitrin decreased the blood and urine alcohol levels in patients with diabetes insipidus and in normal individuals, but in spite of this the symptoms of alcoholic intoxica-

## GASTROSCOPY AND PERITONEOSCOPY

The most useful new adjuncts to diagnosis aside from laboratory tests are the gastroscope and the peritoneoscopy.<sup>2</sup> Lesions within the stomach are often so baffling to the roentgenologist that he welcomes the aid of the gastroscopist. Experience in this field will often lead to a correct interpretation of the pathologic process or lack of it, and thus bring about the logical therapeutic approach. Thus early manifestations of malignancy may be recognized in a curable state, and benign lesions may be treated on a conservative basis with greater assurance of success.

Peritoneoscopy is a comparatively safe and simple procedure. The patient has little discomfort during it, and may be up and about within twenty-four hours. When the usual methods of diagnosis fail to solve an intra-abdominal problem, we can often settle the question by peritoneoscopy. So far, one of its most useful applications has been in advanced carcinoma of the stomach. If there are metastases to the liver or peritoneum exploratory laparotomy should be avoided, since under these circumstances cure is impossible and palliative surgery is rarely worthwhile, also, one third of the patients in this group succumb during their post-operative convalescence. In a high percentage of doubtful cases of cancer of the stomach, Benedict<sup>2</sup> has been able to determine the operability in a correct manner, an accomplishment which has reduced to a minimum the number of useless exploratory laparotomies in this disease. Peritoneoscopy is helpful in many other doubtful intra-abdominal conditions, and more use will be made of it as experience grows and results are properly evaluated.

## HEALING OF WOUNDS

Methods of incision have changed little in many years, and aside from the careful avoidance of nerve injury a surgeon may safely employ any approach to a given area that best suits his purpose. Considerable attention has been given to the use of suture material in connection with the healing of wounds, and it seems that surgery throughout the country is progressing toward those ideal principles so carefully laid down by Halsted more than a quarter of a century ago. Cleanliness, gentleness, sharp dissection, hemostasis, avoidance of dead space and the prevention of foreign bodies in the wound have been accepted as the criteria of good surgery and perfect wound healing. Fine silk, instead of the usual sizes of catgut, causes less foreign-body reaction in the tissues and hence results in better wounds. Fine, malleable steel wire causes even less reaction than silk,

and is favored by some surgeons. In certain types of wounds, particularly where contamination is unavoidable, there is a tendency to employ no sutures except properly placed, through-and-through strands of pure silver wire, or especially treated non-porous, heavy, braided silk, thus avoiding all possibility of foreign material within the wound. Dehiscence, wound infection and hernia in the scar may thus be reduced to a minimum.

## HERNIA

Roscoe Graham's<sup>3</sup> explanation of the mechanism of sliding hernia is of the utmost importance. Sliding hernia of the sigmoid has been particularly difficult to reduce and repair through an inguinal incision alone. The bowel herniates between the leaves of its mesentery, and if the abdominal cavity is opened above through a separate incision and traction is exerted on the sigmoid, the bowel is easily reduced, the two leaves of the mesentery come together in a normal fashion. The defect in the inguinal canal is best repaired through the usual oblique incision after the abdominal incision has been closed.

Williams<sup>4</sup> advocates a more frequent abdominal approach in the repair of inguinal hernia. This is especially advantageous when dealing with undescended testicle and hernia.

Payne<sup>5</sup> and others favor the use of strips of fascia from the external oblique muscle in the repair of femoral hernia. Such strips have been used ever since McArthur suggested them in the repair of the defects of inguinal hernia.

Gallie and Le Mesurier's<sup>6</sup> contribution—the repair of the hernia with strips of fascia lata—has been widely adopted, and with great success. Certainly many defects could not otherwise be corrected.

## APPENDICITIS

The educational campaign against the use of cathartics in acute abdominal discomfort has succeeded in reducing the mortality from appendicitis in Philadelphia.<sup>7</sup> A program of widespread activity in this direction elsewhere throughout the country is in order.

In adult patients with peritonitis complicating appendicitis, there is considerable evidence in favor of delayed surgery. The highest mortality occurs in such patients when operated on between the third and sixth days of the disease. This explains the increasing mortality in acute appendicitis. Many cases are still treated expectantly in the home, even under the guidance of a physician. As soon as rupture has taken place, with the resultant spreading peritonitis, the patient is sent to the hospital, if operation is immediately undertaken.

## REPORT ON MEDICAL PROGRESS

### ABDOMINAL SURGERY

ARTHUR W ALLEN, M D \*

BOSTON

**R**ECENT advances in surgery have been attained through improvements in technical procedures, more perfectly controlled anesthesia and a gradually increasing knowledge of pathologic physiology

#### PREOPERATIVE AND POSTOPERATIVE CARE

We have often seen a well-accomplished surgical operation fail because of improper preparation of the patient and a lack of understanding of the physiological and biochemical factors at fault. Valuable contributions have been made in this field within recent years. Since in such a large proportion of cases the principles involved apply to patients with intra-abdominal lesions, we shall stress their importance in this paper.

It is incredible but true that many surgeons have no hesitation in subjecting patients to a serious abdominal operation in a state of fatigue and general debility, with little or no thought of the effect of the superimposed trauma. Thus, a tired business man or a housewife, having redoubled his or her efforts for days and weeks, enters the hospital late in the day and is subjected to a major operation early the next morning. In casting about for the reasons why such a patient has done poorly after operation, the last thought is usually the obvious one—a tired horse has been entered in a race. This mistake, which is made even by men of high intelligence, is one of the chief causes of disaster. A few days of training in the hospital environment can often be utilized to good advantage. A correction of water and salt balance, a preliminary transfusion, and an evaluation of sedatives in addition to rest and nourishment often make the difference between a smooth and a stormy convalescence, and even between life and death.

In the postoperative care of this patient one must have a baseline from which to start, so that the patient's needs can be met in an orderly manner and not by general rule. Fluid must be administered, but the amount may be too great in a given period for the patient in question, producing a fatal pulmonary edema or cardiac dilatation. Salt must be limited to his physiological needs or water will be retained within the tissues. Glucose

can be utilized up to certain limits, and a moderate excess is offset by loss through the kidneys. A reasonably safe rule is use 50 gm of glucose in each liter of normal saline solution and of distilled water, alternately. A patient with a high intestinal fistula or an inlying Levine tube needs more salt than one whose hydrochloric acid is retained within the intestinal tract. The average adult patient needs approximately 3 liters of fluid, evenly distributed in each twenty-four hours. A rough guide is the urinary output, which should average not less than 1000 cc per day. Depleted patients and those who have had large resections should be routinely transfused, those who have lost an abnormal amount of blood should receive enough to bring the blood content up to a low normal level.

Patients should receive a proper amount of sedatives, if any is to be given, where there is need for maintaining the tone of the small bowel; morphine is the drug of choice. The only guide as to the amount should be the rate of respiration, which should not descend below 12 per minute. Pitressin has been advocated by some observers, its action is primarily upon the large bowel, if used, its administration should be started on the operating table and continued until the need for it has passed, that is for forty-eight or seventy-two hours. If it is given after distention has taken place, a rupture of the large intestine may follow. One must realize that after laparotomy there is a stage of physiologic ileus. Food should be withheld and the tone of the small bowel maintained until normal peristalsis has returned. If this precaution is neglected the patient's abdomen will become distended and vomiting will ensue. Fine and Levenson<sup>1</sup> have contributed much to the problem of gaseous distention after operation. They have shown that milk, orange juice, carbohydrates and protein in the order named, all produce gas. Small amounts of water, followed by consommé, tea, cooked cereal, milk and lime water should be used until intestinal elimination has become adequate. Postoperatively patients should be exercised by deep breathing, frequent turning, and movements of the arms and legs. The restless patient almost never develops phlebitis and pulmonary embolus, while the fat, lethargic individual is prone to do so.

\* Lecturer in surgery, Harvard Medical School; chief of the East Surgical Service, Massachusetts General Hospital.

may be undertaken on an erroneous diagnosis, but few cases should be treated conservatively without the confirmation of paracentesis. Indications for surgery are unrelievable pain and nausea, jaundice, and a palpable mass. Biliary decompression relieves the pain, jejunostomy for feeding and a Levine tube in the stomach relieve the nausea. Drainage of the pancreas itself should be limited to adequate drainage of the lesser peritoneal cavity.

Adenomas of the pancreas are being reported from time to time. These cases are apt to be suspected by the psychiatrist, since the convulsive phase of hyperinsulinism is prone to be interpreted as a form of epilepsy. Marked emaciation and a prolonged false psychosis lead to the wrong interpretation of symptoms. The results in a successful adenectomy are dramatic. The adenomas are often small, and may be situated in the head of the pancreas and on the posterior side. They have a characteristic cherry-red appearance and are usually single. Attempts at subtotal pancreatectomy in the hope of including a small, non-palpable adenoma are apt to be disappointing, since the tumor may well be left in the remaining portion of the organ.

Carcinoma of the pancreas, when limited to a small area near the papilla of Vater, may be brought to light by jaundice while still resectable. Whipple, Parsons and Mullins<sup>11</sup> have developed a rational two stage attack to relieve this situation, and have subjected 8 patients to this procedure, 1 of them lived three years after operation before recurrence in the liver caused death. In this operation the gall bladder is anastomosed to the gastrointestinal tract and the common duct is ligated. At a second operation two weeks later the duodenum and the head of the pancreas are removed en bloc. The duct of the pancreas is carefully ligated, the cut edge of the pancreas is sutured and drainage to this area is established by cigarette wicks. Continuity between the stomach and intestine is established either at the first or the second stage.

Stones in the pancreas are of the same consistence as salivary calculi, and are easily seen in an adequate roentgenogram of the region. Haggard<sup>12</sup> has collected about 140 cases from the literature, and some from his own practice. He concludes that symptoms of continued pain radiating to the back with nausea and vomiting warrant surgical interference. Following operation, fistulas are prone to develop if the stones were in the main duct. Drainage may continue for several years but finally ceases.

#### STOMACH

Ulcers of the stomach should be considered malignant until proved benign. Under ideal treatment the ulcer should heal entirely within six weeks. Ulcers with cancer in them may improve under medical management, as shown by an apparently smaller crater in the roentgenogram and loss of symptoms. This may result in too long an interval between examinations, and the passing by of the stage wherein the lesion is curable by adequate resection. Recurrence of ulceration and profuse bleeding is also an indication for surgery. If the lesion is unquestionably benign, the ulcer may be destroyed by excision or cauterization, combined with some procedure aimed at increasing the alkalinity of the stomach contents. Jejunal ulcers do not occur following gastroenterostomy for gastric ulcer. Polyposis of the stomach, leiomyomas and suspicious ulcerations are best treated by gastrectomy. Polyps bleed and degenerate into malignancy, leiomyomas bleed periodically and spread locally. Questionable ulcerations are often found to be malignant.

Pre-pyloric ulcerations are nearly all malignant, those on the lesser curvature are so in approximately one third the cases.

Carcinoma of the stomach offers an operability of approximately 30 per cent, including the patients subjected to total gastrectomy. Approximately 20 per cent of those surviving subtotal gastrectomy live five years or more after operation.

Twenty-four total gastrectomies have now been done at the Massachusetts General Hospital, in many of the cases the prognosis was unfavorable from the beginning. The operative mortality is still 50 per cent, owing to the inclusion of cases with pancreatic and colonic involvement. The survivors had a more comfortable life, varying from a few months to four and a half years. Those dying of liver recurrence had a more comfortable exitus than did those beyond the reach of resection who died of starvation. Jejunoesophageostomy, enteroenterostomy between the loops of the jejunum and jejunostomy for feeding formed the best combination of procedures. The loop of the jejunum is attached to the diaphragm by a row of sutures running entirely around the anastomosis between the end of the esophagus and the side of the jejunum.

#### DUODENUM

Ulcer of the duodenum is a medical problem. The complications warrant surgical interference. In the first place, acute perforation must be closed, the simplest method is that described by

death is more likely than at any other stage of the disease. Conservative physicians in previous decades continued their expectant type of treatment at home until there was spontaneous cure, or death occurred, or an obvious localized abscess developed. Under this regime the mortality was lower than it is at present. Thus it has become apparent that there is a stage of spreading peritonitis which is better treated by supportive measures until localization has taken place. Children do not seem to tolerate this method of treatment as well as do adults.

The general attitude on drainage of the abdominal cavity in appendicitis has changed decidedly. There was a time when the dictum was, "In case of doubt, drain"; it is now definitely the reverse. Except in cases with the formation of a localized abscess, drainage is contraindicated. The excess fluid may be aspirated with care and gentleness with the suction tip, and the peritoneum sutured tightly. The contaminated layers of the abdominal wall are often drained to advantage.

The detailed modern adaptation of Ochsner's regime has become of great importance in the successful management of peritoneal involvement, both as a preventive and as a curative procedure.

#### BILIARY SYSTEM

The tendency of patients with obstructive jaundice to bleed can now be controlled by the use of vitamin K and cholecystic acid. Careful laboratory studies by Stewart<sup>8</sup> and others indicate that the dosage of this vitamin and the period of time necessary to prepare such patients for operation will soon be standardized. So far, this substance cannot be obtained commercially, but it will be forthcoming at an early date. The laboratory test for the prothrombin level of the blood will soon be a matter of routine. Thus one of the chief causes of death in obstructive jaundice will be eliminated.

Much evidence has been submitted in favor of early operation in acute gall-bladder disease. It appears that the mortality in cases so treated is lower than in similar groups in which the surgeon postpones operation in the hope that the disease will quiet down. These cases are not emergency ones, to be operated on at night with inadequate assistance, but should be evaluated after dehydration has been combated. If greatly improved in twelve hours as indicated by less fever, a decrease in leukocytosis and local tenderness, one may safely wait longer, in the majority of cases the patient will come to operation a week or ten days after the acute onset in a better condition for operation. The gangrenous gall bladders that need early surgery do not quiet down, but the high white-cell count, fever and local tenderness per-

sist after the loss of fluid has been offset. In these cases operation should be carried out as soon as reasonably ideal conditions can be obtained.

In cases of chronic gall-bladder disease, artificial edema greatly facilitates the preservation of an adequate amount of serous coat for peritonization of the hepatic fissure. This was brought to my attention by Dr Alfred M Rowley,<sup>9</sup> of Hartford, Connecticut, and was probably first suggested by Bevan.<sup>10</sup> Salt solution injected through a fine needle beneath the serous covering of the gall bladder makes its enucleation much easier—whether this is done from the fundus toward the ducts or from below upward. We have all become conscious of the importance of the common duct, and in diseases of the biliary tract realize that injury to this structure must be avoided at all costs. Anomalies of the ducts and the blood supply are found more frequently than has been realized. A Russian anatomist reports 10 per cent of anomalies in a large number of dissections. There are fewer injuries to the common duct if the gall bladder is carefully and bloodlessly dissected out from the fundus toward the ducts. One disadvantage of this method is the possibility of forcing small stones through the cystic duct into the common duct, but this can often be prevented by placing a clamp on the cystic duct before beginning the dissection. The common duct should be explored and its outlet into the duodenum gently and gradually dilated with suitable bougies, if necessary. The width of dilatation of the sphincter of Oddi should always be less than the diameter of the duct, and never more than the size of the stones that might be hidden within the hepatic ducts. A 7-mm. Bake's dilator or a No 21 French bougie is usually adequate. Indications for exploration of the duct are numerous. Frequent attacks of pain, vomiting, chills and fever, jaundice, small stones, a large cystic duct, a large or thickened common duct, thickening in the head of the pancreas, palpable stones within the ducts and a stoneless gall bladder are some of the commoner reasons for exploration. Over one third of the gall-bladder operations at the Massachusetts General Hospital are accompanied by duct exploration, and in approximately one third of these, stones are removed.

#### PANCREAS

In acute pancreatitis there is a tendency toward a nonoperative, supportive type of treatment. The diagnosis is often difficult, but can finally be determined by paracentesis with a small needle. If thin, bloody fluid is obtained in the presence of other adequate symptoms and signs, the diagnosis should be considered as established. Operation

may be undertaken on an erroneous diagnosis, but few cases should be treated conservatively without the confirmation of paracentesis. Indications for surgery are unrelievable pain and nausea, jaundice, and a palpable mass. Biliary decompression relieves the pain, jejunostomy for feeding and a Levine tube in the stomach relieve the nausea. Drainage of the pancreas itself should be limited to adequate drainage of the lesser peritoneal cavity.

Adenomas of the pancreas are being reported from time to time. These cases are apt to be suspected by the psychiatrist, since the convulsive phase of hyperinsulinism is prone to be interpreted as a form of epilepsy. Marked emaciation and a prolonged false psychosis lead to the wrong interpretation of symptoms. The results in a successful adenectomy are dramatic. The adenomas are often small, and may be situated in the head of the pancreas and on the posterior side. They have a characteristic cherry-red appearance and are usually single. Attempts at subtotal pancreatectomy in the hope of including a small, non-palpable adenoma are apt to be disappointing, since the tumor may well be left in the remaining portion of the organ.

Carcinoma of the pancreas, when limited to a small area near the papilla of Vater, may be brought to light by jaundice while still resectable. Whipple, Parsons and Mullins<sup>11</sup> have developed a rational two-stage attack to relieve this situation, and have subjected 8 patients to this procedure, 1 of them lived three years after operation before recurrence in the liver caused death. In this operation the gall bladder is anastomosed to the gastrointestinal tract and the common duct is ligated. At a second operation two weeks later the duodenum and the head of the pancreas are removed en bloc. The duct of the pancreas is carefully ligated, the cut edge of the pancreas is sutured and drainage to this area is established by cigarette wicks. Continuity between the stomach and intestine is established either at the first or the second stage.

Jejunal ulcers do not occur following gastroenterostomy for gastric ulcer. Polyposis of the stomach, leiomyomas and suspicious ulcerations are best treated by gastrectomy. Polyps bleed and degenerate into malignancy, leiomyomas bleed periodically and spread locally. Questionable ulcerations are often found to be malignant.

Pre-pyloric ulcerations are nearly all malignant, those on the lesser curvature are so in approximately one third the cases.

Carcinoma of the stomach offers an operability of approximately 30 per cent, including the patients subjected to total gastrectomy. Approximately 20 per cent of those surviving subtotal gastrectomy live five years or more after operation.

Twenty-four total gastrectomies have now been done at the Massachusetts General Hospital, in many of the cases the prognosis was unfavorable from the beginning. The operative mortality is still 50 per cent, owing to the inclusion of cases with pancreatic and colonic involvement. The survivors had a more comfortable life, varying from a few months to four and a half years. Those dying of liver recurrence had a more comfortable exitus than did those beyond the reach of resection who died of starvation. Jejunoesophagostomy, enteroenterostomy between the loops of the jejunum and jejunostomy for feeding formed the best combination of procedures. The loop of the jejunum is attached to the diaphragm by a row of sutures running entirely around the anastomosis between the end of the esophagus and the side of the jejunum.

#### DUODENUM

Ulcer of the duodenum is a medical problem. The complications warrant surgical interference. In the first place, acute perforation must be closed, the simplest method is that described by

Roscoe Graham,<sup>13</sup> which consists of holding a graft from the omentum over the opening by means of sutures passed above, below and through the ulcer and tied loosely over the graft

Secondly, cicatricial obstruction may take place when the ulcer is near the pylorus and the condition has had many flares and cures. This is a mechanical problem occurring mainly in patients beyond middle life, the condition responds well to simple gastroenterostomy or pyloroplasty

Thirdly, profuse bleeding is usually associated with ulcers of the posterior wall which have eroded the pancreaticoduodenal artery. Spontaneous remission usually occurs in patients under fifty years of age. If they are nearing this age, a radical attempt to rid them of the tendency to ulcer should be made in a quiescent stage—usually not under six weeks from a given period of severe bleeding. The tendency for ulcers to recur and to become intractable to conservative measures is due to their deep penetration into the pancreas and the complete loss of continuity of the duodenum in this area. Patients over fifty years of age with this lesion have enough rigidity in the wall of the bleeding vessel to interfere with the organization of an adequate clot, and death from hemorrhage occurs in one third of these cases. Radical operation during the phase of bleeding is rarely indicated, but when it is, the indication is definite, and the operation if undertaken within forty-eight hours of the onset of hemorrhage carries little more risk than does an operation by election

Fourthly, intractable symptoms occur in about 5 per cent of duodenal ulcerations. These may be due to economic or social circumstances. Radical subtotal gastrectomy is indicated in such cases. This should include the excision of all the gastric mucosa from the pylorus to the junction of the middle and upper thirds of the stomach, and of the first portion of the duodenum when practical

Fifthly, gastrojejunal ulcers rarely respond well to conservative measures. If bleeding and pain persist and roentgenograms show no progress, surgery should be undertaken. When feasible a subtotal gastrectomy should be done. If operation is postponed a gastrojejunocolic fistula may develop, and surgery then becomes imperative and increasingly dangerous. The fistula should be excised in an aseptic manner, with the restoration of normal function. After recovery from the operation, reactivation of the original duodenal ulcer is liable to occur, then a subtotal gastrectomy in a clean field gives maximum protection

#### REGIONAL ENTERITIS

Regional enteritis has become a recognized entity. Long classified as non-specific granuloma

and often diagnosed clinically as tuberculosis, it follows a pattern sufficiently definite to warrant considerable interest. The symptoms are vague and somewhat variable. Abdominal pain with diarrhea, loss of weight and tenderness in the right lower quadrant are often followed by the formation of an abscess, with ultimate fistulous tracts running to the perineum or to a previous exploratory or appendectomy incision. The commonest site is the terminal ileum, but the cecum is often involved. Other segments of small intestine are affected at times, and more rarely segments of the colon become diseased. Reichert and Mathes<sup>14</sup> have reproduced a similar condition in animals by injecting the lymphatics of the ileocecal region. Crohn, Ginzburg and Oppenheimer<sup>15</sup> have done much to clarify the pathologic picture and have added greatly to the knowledge of the disease. The etiology remains unknown. The most successful form of treatment thus far employed is a wide, radical resection of the diseased bowel with its node-bearing areas. Mixter<sup>16</sup> has reported a series of approximately 20 cases so treated, with excellent results. Recurrence occurs in a certain proportion of cases, it may be due to inadequate removal of the lymphatics, or to the inclusion in the resected portion of an insufficient margin of apparently normal bowel

#### COLON

Idiopathic ulcerative colitis warrants permanent ileostomy in approximately one third of the cases, and according to McKittrick and Miller<sup>17</sup> about half these patients require total colectomy before they can lead reasonably normal lives. Patients with this condition should not be allowed to become too ill or depleted before one resorts to surgery, or the mortality will be unjustifiably high

Polyposis involving all or various segments of the colon justifies colectomy. There is a marked familial tendency in this disease. The rectum can be saved in many cases, and the polyps in this segment can be watched and fulgurated at intervals through the proctoscope

Carcinoma of the colon is a frequent condition, and such a lesion should be suspected if there is any change in bowel habit, blood or mucus in the stools, anemia associated with disturbances of the digestive tract, or a palpable intra-abdominal mass, loss of weight and obstructive symptoms indicate an advanced lesion, often inoperable. The total operability, however, is high,—over 70 per cent,—as is the curability—over 50 per cent. The operative mortality averages 15 per cent

The right colon should be resected in two stages. A preliminary ileotransverse colostomy should be followed ten or fourteen days later by a

colectomy on the right. The supposition of protection of the peritoneum by a previous operation is substantiated by research in this field by Collier, Ransom and Rife<sup>18</sup>. Lesions in the transverse colon should be attacked by a preliminary proximal drainage. The left colon may be decompressed by cecostomy, and this has been a very satisfactory procedure preliminary to resection. With the use of a large tube the colon can be adequately prepared, and by infolding the cecum on the tube at the time of cecostomy, it can be made to heal spontaneously when no longer needed. Devine<sup>19</sup> has recently described a method of "defunctioning" the diseased left colon and rectum by a preliminary double-barreled proximal transverse colostomy. The bowel is divided between clamps with a cautery, and the limbs of the bowel are sutured together over a distance of 8 cm., the ends being left long enough to be brought to the surface and separated by the entire abdominal wall. The distal segment can be irrigated so that in two or three weeks it is actually free of infection. The diseased bowel is then resected through a clean field. When the need of the proximal colostomy has passed, the spur is crushed by special clamps, the blades of which are applied separately and then brought into contact from the surface. This method has much to commend it and is likely to be extensively used, especially by those who have not perfected aseptic anastomosis and those who have been disappointed in the adequate functioning of cecostomy.

Modifications of the Parker-Kerr type of aseptic intestinal anastomosis have given the lowest mortality of any method used at the Massachusetts General Hospital. Accurate attention to details in the technic is essential, and if properly executed these procedures will yield excellent results.

#### CARCINOMA OF THE RECTUM

Radical combined abdominoperineal resection after the method of Miles<sup>20</sup> is the procedure of choice. It can be safely applied to approximately 75 per cent of cases. Careful preoperative preparation, attention to technical details, spinal anesthesia and supportive postoperative measures have reduced the mortality to approximately 10 per cent. Patients who are poor risks, those with large infiltrating lesions and those with any degree of obstruction should be operated on in two stages. The preliminary stage may be any of the proximal drainage procedures that are found effective in the hands of the operator. Devine's<sup>19</sup> defunctioning transverse colostomy more nearly meets all requirements than any other so far advocated.

#### INTESTINAL OBSTRUCTION

The application of continuous suction to an intubated stomach catheter, as employed by Wangersteen and Paine,<sup>21</sup> has eliminated the need of many operations for ileus. If the obstruction is complete and of a mechanical nature, this procedure may be carried on to a period when operative interference is impossible. In maintaining the body fluids and salts and supporting the patient by blood transfusions, one may not realize that obstruction exists. Thus if the total fluids withdrawn from the upper gastrointestinal tract are closely watched, and a time limit of not more than three days of such treatment is set, the opportunity for surgical intervention will not be lost.

Miller and Abbott<sup>22</sup> have devised an ingenious long triple tube of nasal-catheter size that can be introduced slowly and, by the aid of a small balloon near the tip, passed all the way down through the intestine. That this tube should pass down the intestine and at the same time allow suction of fluid contents seems amazing. That it will in certain cases reach the actual point of obstruction, and in cases where the obstruction is not complete will relieve the patient and avoid a dangerous operation, is an established fact. Practice is necessary to get the end of the tube through the pylorus, and frequent roentgenograms are needed until this has been accomplished. Dr. George W. Holmes<sup>23</sup> has made the helpful suggestion that iced drinks will cause the pylorus to open and this point may be of great aid in the successful use of the tube. Scudder, Zwemer and Truszkowski<sup>24</sup> have studied a large series of cases of intestinal obstruction. Many of the symptoms in these patients, they found, are due to a heightened blood-potassium level. This may be produced in other ways, such as fistula of the small bowel, adrenal insufficiency and potassium poisoning. Lethal levels of blood potassium are frequently found as a result of experimental obstruction, and occasionally in patients. Rapid return to a normal level follows operative removal of the obstruction.

#### MECKEL'S DIVERTICULUM

In adults, this condition is rarely diagnosed correctly before operation. In the acute stage of inflammation the preoperative diagnosis is usually intestinal obstruction. In children the diagnosis is frequently made on the basis of abdominal pain and blood in the stools. Owing to embryonal rests of gastric mucosa within the diverticulum, all the symptoms and signs of so-called peptic ulcer may be present—even, on occasion, those of acute perforation. One of the most

Roscoe Graham,<sup>13</sup> which consists of holding a graft from the omentum over the opening by means of sutures passed above, below and through the ulcer and tied loosely over the graft

Secondly, cicatricial obstruction may take place when the ulcer is near the pylorus and the condition has had many flares and cures. This is a mechanical problem occurring mainly in patients beyond middle life, the condition responds well to simple gastroenterostomy or pyloroplasty.

Thirdly, profuse bleeding is usually associated with ulcers of the posterior wall which have eroded the pancreaticoduodenal artery. Spontaneous remission usually occurs in patients under fifty years of age. If they are nearing this age, a radical attempt to rid them of the tendency to ulcer should be made in a quiescent stage—usually not under six weeks from a given period of severe bleeding. The tendency for ulcers to recur and to become intractable to conservative measures is due to their deep penetration into the pancreas and the complete loss of continuity of the duodenum in this area. Patients over fifty years of age with this lesion have enough rigidity in the wall of the bleeding vessel to interfere with the organization of an adequate clot, and death from hemorrhage occurs in one third of these cases. Radical operation during the phase of bleeding is rarely indicated, but when it is, the indication is definite, and the operation if undertaken within forty-eight hours of the onset of hemorrhage carries little more risk than does an operation by election.

Fourthly, intractable symptoms occur in about 5 per cent of duodenal ulcerations. These may be due to economic or social circumstances. Radical subtotal gastrectomy is indicated in such cases. This should include the excision of all the gastric mucosa from the pylorus to the junction of the middle and upper thirds of the stomach, and of the first portion of the duodenum when practical.

Fifthly, gastrojejunal ulcers rarely respond well to conservative measures. If bleeding and pain persist and roentgenograms show no progress, surgery should be undertaken. When feasible a subtotal gastrectomy should be done. If operation is postponed a gastrojejuno-colic fistula may develop, and surgery then becomes imperative and increasingly dangerous. The fistula should be excised in an aseptic manner, with the restoration of normal function. After recovery from the operation, reactivation of the original duodenal ulcer is liable to occur, then a subtotal gastrectomy in a clean field gives maximum protection.

#### REGIONAL ENTERITIS

Regional enteritis has become a recognized entity. Long classified as non-specific granuloma

and often diagnosed clinically as tuberculosis, it follows a pattern sufficiently definite to warrant considerable interest. The symptoms are vague and somewhat variable. Abdominal pain with diarrhea, loss of weight and tenderness in the right lower quadrant are often followed by the formation of an abscess, with ultimate fistulous tracts running to the perineum or to a previous exploratory or appendectomy incision. The commonest site is the terminal ileum, but the cecum is often involved. Other segments of small intestine are affected at times, and more rarely segments of the colon become diseased. Reichert and Mathes<sup>14</sup> have reproduced a similar condition in animals by injecting the lymphatics of the ileocecal region. Crohn, Ginzburg and Oppenheimer<sup>15</sup> have done much to clarify the pathologic picture and have added greatly to the knowledge of the disease. The etiology remains unknown. The most successful form of treatment thus far employed is a wide, radical resection of the diseased bowel with its node-bearing areas. Mixer<sup>16</sup> has reported a series of approximately 20 cases so treated, with excellent results. Recurrence occurs in a certain proportion of cases, it may be due to inadequate removal of the lymphatics, or to the inclusion in the resected portion of an insufficient margin of apparently normal bowel.

#### COLON

Idiopathic ulcerative colitis warrants permanent ileostomy in approximately one third of the cases, and according to McKittrick and Miller<sup>17</sup> about half these patients require total colectomy before they can lead reasonably normal lives. Patients with this condition should not be allowed to become too ill or depleted before one resorts to surgery, or the mortality will be unjustifiably high.

Polyposis involving all or various segments of the colon justifies colectomy. There is a marked familial tendency in this disease. The rectum can be saved in many cases, and the polyps in this segment can be watched and fulgurated at intervals through the proctoscope.

Carcinoma of the colon is a frequent condition, and such a lesion should be suspected if there is any change in bowel habit, blood or mucus in the stools, anemia associated with disturbances of the digestive tract, or a palpable intra-abdominal mass, loss of weight and obstructive symptoms indicate an advanced lesion, often inoperable. The total operability, however, is high,—over 70 per cent,—as is the curability—over 50 per cent. The operative mortality averages 15 per cent.

The right colon should be resected in two stages. A preliminary ileotransverse colostomy should be followed ten or fourteen days later by a

colectomy on the right. The supposition of protection of the peritoneum by a previous operation is substantiated by research in this field by Collier, Ransom and Rife<sup>15</sup>. Lesions in the transverse colon should be attacked by a preliminary proximal drainage. The left colon may be decompressed by cecostomy, and this has been a very satisfactory procedure preliminary to resection. With the use of a large tube the colon can be adequately prepared, and by infolding the cecum on the tube at the time of cecostomy, it can be made to heal spontaneously when no longer needed. Devine<sup>19</sup> has recently described a method of "defunctioning" the diseased left colon and rectum by a preliminary double-barreled proximal transverse colostomy. The bowel is divided between clamps with a cautery, and the limbs of the bowel are sutured together over a distance of 8 cm., the ends being left long enough to be brought to the surface and separated by the entire abdominal wall. The distal segment can be irrigated so that in two or three weeks it is actually free of infection. The diseased bowel is then resected through a clean field. When the need of the proximal colostomy has passed, the spur is crushed by special clamps, the blades of which are applied separately and then brought into contact from the surface. This method has much to commend it and is likely to be extensively used, especially by those who have not perfected aseptic anastomosis and those who have been disappointed in the adequate functioning of cecostomy.

Modifications of the Parker-Kerr type of aseptic intestinal anastomosis have given the lowest mortality of any method used at the Massachusetts General Hospital. Accurate attention to details in the technic is essential, and if properly executed these procedures will yield excellent results.

#### CARCINOMA OF THE RECTUM

Radical combined abdominoperineal resection after the method of Miles<sup>20</sup> is the procedure of choice. It can be safely applied to approximately 75 per cent of cases. Careful preoperative preparation, attention to technical details, spinal anesthesia and supportive postoperative measures have reduced the mortality to approximately 10 per cent. Patients who are poor risks, those with large infiltrating lesions and those with any degree of obstruction should be operated on in two stages. The preliminary stage may be any of the proximal drainage procedures that are found effective in the hands of the operator. Devine's<sup>19</sup> defunctioning transverse colostomy more nearly meets all requirements than any other so far advocated.

#### INTESTINAL OBSTRUCTION

The application of continuous suction to an intubing stomach catheter, as employed by Wangensteen and Paine,<sup>21</sup> has eliminated the need of many operations for ileus. If the obstruction is complete and of a mechanical nature, this procedure may be carried on to a period when operative interference is impossible. In maintaining the body fluids and salts and supporting the patient by blood transfusions, one may not realize that obstruction exists. Thus if the total fluids withdrawn from the upper gastrointestinal tract are closely watched, and a time limit of not more than three days of such treatment is set, the opportunity for surgical intervention will not be lost.

Miller and Abbott<sup>22</sup> have devised an ingenious long triple tube of nasal-catheter size that can be introduced slowly and, by the aid of a small balloon near the tip, passed all the way down through the intestine. That this tube should pass down the intestine and at the same time allow suction of fluid contents seems amazing. That it will in certain cases reach the actual point of obstruction, and in cases where the obstruction is not complete will relieve the patient and avoid a dangerous operation, is an established fact. Practice is necessary to get the end of the tube through the pylorus, and frequent roentgenograms are needed until this has been accomplished. Dr. George W. Holmes<sup>23</sup> has made the helpful suggestion that iced drinks will cause the pylorus to open and this point may be of great aid in the successful use of the tube. Scudder, Zwemer and Truszkowski<sup>24</sup> have studied a large series of cases of intestinal obstruction. Many of the symptoms in these patients, they found, are due to a heightened blood-potassium level. This may be produced in other ways, such as fistula of the small bowel, adrenal insufficiency and potassium poisoning. Lethal levels of blood potassium are frequently found as a result of experimental obstruction, and occasionally in patients. Rapid return to a normal level follows operative removal of the obstruction.

#### MECKEL'S DIVERTICULUM

In adults, this condition is rarely diagnosed correctly before operation. In the acute stage of inflammation the preoperative diagnosis is usually intestinal obstruction. In children the diagnosis is frequently made on the basis of abdominal pain and blood in the stools. Owing to embryonal rests of gastric mucosa within the diverticulum, all the symptoms and signs of so-called peptic ulcer may be present—even, on occasion, those of acute perforation. One of the most

reliable diagnostic points is tenderness directly beneath the umbilicus

#### CALCIFIED MESENTERIC LYMPH NODES

This condition is so frequently seen in patients without abdominal symptoms that inadequate significance has been attached to it. Calcification is probably the result of healing in certain cases of mesenteric adenitis. Approximately 80 per cent of children having calcified nodes on routine examination have no history of any prolonged abdominal symptoms. In the remaining 20 per cent, half of them become symptom-free in a period varying from a few months to a few years on a conservative dietary and hygienic regime. In a small number of cases symptoms persist into adult life. The symptoms are those of vague abdominal discomfort that may occur daily without actual interference with routine life or may cause recurring bouts of acute abdominal pain with nausea and vomiting. Appendectomy is often done during or following one of these acute episodes. The attacks may recur with such frequency and so little attention be paid to them by the physician that the patient is labeled a neurasthenic or hypochondriac. Careful evaluation is justifiable and, in certain cases, excision of the calcified masses is followed by a complete relief of symptoms and a restoration to robust health of an individual previously handicapped by chronic invalidism. The tenderness usually starts just at the right of and slightly below the umbilicus, and extends toward the left upper quadrant, following closely the mesenteric vessels. In a group of such adult and adolescent patients studied by Allen and Howe<sup>25</sup> at the Massachusetts General Hospital, it was found that appendectomy alone relieved

50 per cent. Appendectomy and excision of the chief mass of calcified nodes relieved 95 per cent. Those unrelieved were found to have such an extensive distribution that removal of the nodes was impracticable.

## CASE 25071

## PRESENTATION OF CASE

A twenty-year-old, single Russian Jewess was admitted complaining of pain and swelling just below the right knee.

About five months prior to admission the patient first noticed that while climbing stairs she had pain in the right leg just below the knee. About one month later she noted the appearance of a swelling over the painful area. The swelling was tender, the tenderness being most marked along the upper anterior surface of the left tibia. This swelling gradually increased. At times it was hot and red. She noted most discomfort in climbing stairs, running, or bending over.

In the past she had been in good health except for diphtheria two years before entry. Her tonsils had been removed about two years before admission. The family history revealed no evidence of familial disease.

Physical examination showed a well-developed and nourished woman in no acute distress. Examination of the head, neck, chest and abdomen was negative. The blood pressure was 118 systolic, 72 diastolic. On the right leg, just below the tibial tubercle, there was a hard, bony swelling about 2 cm in diameter. It was tender to pressure. The skin was not red or edematous. There was no fluctuation. All motion of the knee was normal.

The temperature was 97.8°F., the pulse 72, and respirations 17.

Examination of the urine was negative. The blood showed a red-cell count of 5,000,000 with 85 per cent hemoglobin, and a white-cell count of 8600 with 72 per cent polymorphonuclears. A blood Hinton test was negative.

X-rays showed a cyst-like area of decreased density, about 3 cm in diameter, 5 cm below the proximal epiphyseal line of the right tibia. The lesion was anterior and medial, bulging above the surface of the remainder of the bone. The cortex was markedly thinned in this area. There was increased density of the bone surrounding the lesion. No changes were visible in the soft tissues.

The patient's chart remained normal. On the fourth hospital day an operation was performed.

## DIFFERENTIAL DIAGNOSIS

DR. CHANNING C. SIMMONS: There are a few data that I should have liked to have but which are not available: first, x-rays of the other bones, secondly, the blood-chemistry findings, thirdly, a more detailed history, and, finally, a more careful physical examination, although presumably it was negative.

This is the x-ray film of the lesion. It is evident that this patient had a lesion in the upper end of the tibia situated about 5 cm below the knee joint. In all cases of bone tumor three chief conditions should be considered. First, is it a metabolic or generalized bone disease, such as osteitis fibrosa or Paget's disease? Secondly, is it an inflammatory condition, such as tuberculosis, syphilis or osteomyelitis? Thirdly, is it tumor, either primary or metastatic?

Let us take up the first group—the metabolic diseases. We have nothing that points to such a condition, although I should like information on several blood constituents and more data on the differential count. We also should have x-rays of the other bones, to rule out the possibility of generalized disease. If the tests were all negative, and we may assume they were, I think we can exclude the various metabolic diseases. The patient is young for Paget's disease.

The chief inflammatory conditions to be considered are tuberculosis, syphilis, which is always a possibility, and osteomyelitis. The Hinton test was negative, this presumably rules out syphilis, although in bone syphilis serological tests are negative in 35 or 40 per cent of the cases. There is nothing else that points toward syphilis. I am sorry to say, I am not very conversant with the radiological appearance of tuberculosis, but to me the film does not suggest it. I should expect more change in the joint, and more physical disability than she had. Osteomyelitis may be anything from the acute form to the chronic form known as Brodie's abscess. With that condition we usually have a history of respiratory infection such as tonsillitis, nasal infection or pneumonia preceding the attack of bone pain. She gives no history of such. In Brodie's abscess the x-ray film shows a bony defect with thickening of the bone about it, such as this film shows, so such a diagnosis has to be seriously considered. Usually, however, there is some systemic reaction. The white count should be 10,000 or 12,000 rather than 8000, and the temperature slightly elevated rather than 97.8°F. I should rule out tuberculosis and

syphilis and leave osteomyelitis to be considered later

There is no evidence in the physical examination of a primary tumor of which this might be a metastasis. Of the primary tumors of bone one would have to consider the nonmalignant and the malignant tumors. The nonmalignant types include osteoma, solitary bone cyst, which one may call tumor, and osteochondroma, which might occur in that region, though most chondromas give less the effect of thickening of the bone about the lesion. Another form of tumor is the subperiosteal cyst found in cases of neurofibromatosis, this patient had no areas of pigmentation on her body and no subcutaneous neurofibromas.

Of the malignant tumors to be considered the first is osteogenic sarcoma which usually shows bone destruction and bone formation, but there is no reactive triangle such as one usually sees. Ewing's sarcoma rarely arises in this location and usually shows more bone destruction, although atypical radiographs are not uncommon. It might be an osteogenic sarcoma but I doubt it.

My opinion is that this is either a Brodie's abscess or a chondromatous tumor with a superimposed inflamed bursa. I think a personal examination of the case would have made the diagnosis easier.

DR. TRACY B. MALLORY: Have you any comment, Dr. Hampton?

DR. AUBREY O. HAMPTON: The only thing I can add is that if we had films to show the regional soft tissue over that lesion we should see subcutaneous edema above and below, which would probably rule out tumor and make it more likely to be inflammatory. Furthermore, the dense margin around the bony defect ought to be thinner if it were due to chondroma. I should agree with Dr. Simmons that the lesion is probably a Brodie's abscess.

#### CLINICAL DIAGNOSIS

Brodie's abscess of tibia

#### DR. SIMMONS'S DIAGNOSIS

Brodie's abscess of tibia?

Chondroma of tibia?

#### ANATOMICAL DIAGNOSIS

Localized fibrous osteodystrophy of tibia

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: I am sorry Dr. Sumner M. Roberts is not here to describe first-hand his operative findings. He explored this lesion and found a very thin shell of cortical bone. Underneath, and apparently quite separate from the cortical bone,

was a spherical tumor mass which was fairly firm and felt rather gritty. This was dissected out and Dr. Benjamin Castleman, who was called over to examine it, thought that it looked in gross very much like the lesions which Jaffe<sup>1</sup> in New York has described as osteoid osteoma (Fig. 1). When the sections came through it

Figure 1 Tumor and Overlying Cortical Bone

was found that the mass consisted of rather acellular fibrous tissue containing numerous narrow trabeculae of bone. In a few areas there was a little active bone formation but for the most part it was completely inactive. We puzzled a great deal over the slides and eventually sent them to Dr. Jaffe who finally made a diagnosis of a localized fibrous osteodystrophy, whatever that may mean. The histologic picture is essentially the same as the one a colleague of Dr. Jaffe's, Lichtenstein,<sup>2</sup> has described in a number of cases presenting the syndrome that Dr. Fuller Albright<sup>3</sup> has made familiar to all of us.

DR. HAMPTON: Was there any evidence of inflammation?

DR. MALLORY: Not the slightest. The patient was not worked up as thoroughly as might have been desired, either preoperatively or postoperatively, but so far as is known she had no lesion in other bones and left the hospital perfectly well.

DR. GEORGE W. HOLMES: Could this be related to subchondral necrosis? It is pretty close to that region of the tibia.

DR. MALLORY: At the time of examination there was no evidence of necrosis, but that does not rule out the possibility that there may have been some in the past.

DR. HOLMES Your pathological description sounds very much like the subchondromal necrosis of Pick or osteochondritis

DR. MALLORY I feel so relatively unfamiliar with that condition that I do not believe I can rule it out with certainty, although it does not correspond to my impression of osteochondritis

DR. SIMMONS The pathologic picture would not fit in with von Recklinghausen's disease or subperiosteal neurofibromatosis<sup>2</sup>

DR. MALLORY Again I cannot answer I see no reason why a primary fibroma occurring within the bone might not show foci of ossification It is conceivable that that might be the situation here

DR. HAMPTON It would not show a dense margin in the bone defect. I cannot imagine a benign lesion in the bone that would produce an area of new bone, 2 cm in width, around it. Pressure necrosis is not like that This bone defect has a very definite margin, a thick margin, much thicker than the cysts in Albright's disease I cannot conceive of a tumor producing this picture Can you, Dr. Holmes?

DR. HOLMES No

DR. MALLORY Our thought on the whole was that it probably was not neoplasm, but we have not the slightest idea what is back of it It certainly appears to be a benign lesion, and I have no doubt she is cured

DR. GRANTLEY TAYLOR I should like to know about the Hinton test in bone syphilis

DR. MALLORY Without having looked the matter up I should be inclined to differ with Dr. Simmons on that, and say that the Hinton test is usually positive in bone syphilis, although I have seen cases in which the Hinton test was negative and the Wassermann positive There is a slight danger in regard to the Hinton test it is so sensitive that there is occasionally a pre-zone phenomenon, just as in the Widal reaction, and a negative reading is obtained in a case which really is too strongly positive to show

DR. SIMMONS I might say that I was quoting the late Dr. C. Morton Smith when I made the statement

DR. FULLER ALBRIGHT Why is this not a Brodie's abscess?

DR. MALLORY Because it shows no trace of inflammation I find it hard to believe that an infectious lesion of the bone could heal and not leave behind even a lymphocyte

DR. ALBRIGHT I should think it could in time

DR. HAMPTON She had clinical evidence of inflammation, and it seems as though the lesion should have been inflammatory

DR. SIMMONS Could it not have been a bursa?

DR. MALLORY Nothing is said in the operative note about a bursa

DR. SIMMONS No, but it might have quieted down

## CASE 25072

### PRESENTATION OF CASE

An eighteen-year-old girl was admitted complaining of swelling above the right elbow

About eight weeks before entry she first noted a lump deep in her right upper arm just above the elbow It was not tender or painful and had not changed in size She consulted a physician, following which fifteen doses of x-ray therapy were given over the area The treatment blanched the skin but did not change the size of the tumor She had had no other symptoms

About eleven weeks before admission, during the New England hurricane, she received lacerations of the head and left leg, but remembers no injury or pain involving the right arm The swelling had interfered in no way with the use of the arm The past history and family history were noncontributory

Physical examination showed a well-developed and nourished girl in no distress The general physical examination was negative except that the skin showed acne over the face, back and chest The blood pressure was 115 systolic, 60 diastolic There was a 4 by 5 cm swelling involving the right humerus just above the elbow The skin over this area was mottled and depigmented No axillary nodes could be made out

The temperature was 98.6°F, the pulse 90, and respirations 20

Examination of the urine was negative. The blood had a serum-calcium of 11.1 mg per cent, a phosphorus of 4.2 mg per cent, and a phosphatase of 38 units

Films brought in by the patient, taken before x-ray treatment, showed an area of destruction with ill-defined margins, involving the lateral cortex of the lower end of the right humerus (Fig. 1) This defect was about 4 cm in length, and there was no new bone formation or calcification within the soft tissues The soft-tissue mass was about 5 cm in diameter It was not present at the site of bone destruction The films

taken on admission showed a sharply defined concave defect in the lower end of the right humerus, measuring 4 cm in length and 1 cm in depth (Fig 2) Opposite this defect there was a thin shallow bone which at each end was continuous with the periosteum This shallow bone

phosphorus and phosphatase were all within normal limits The only other relevant preoperative information was contributed by the x-ray films, and I think we might see them before we go farther

In the original film there is no evidence of repair, regenerative activity or encapsulation and we are dealing simply with an area of destruction chiefly confined to the cortical bone Dr Simmons presented in his discussion of the previous case the main pathological categories which we present to ourselves in an attempt to arrive at a diagnosis The constitutional and systemic diseases, of which hyperparathyroidism is a type, usually give some indication by x-ray of the presence of other bone lesions, or betray their pres-

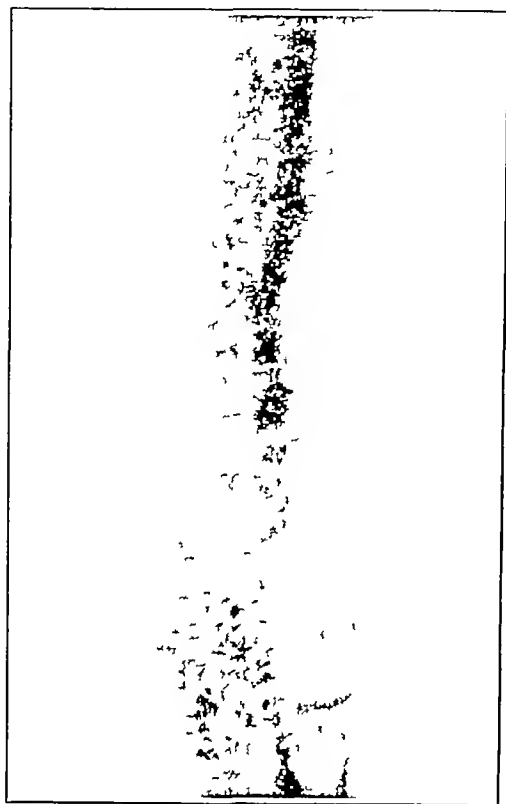

Figure 1 X-Ray Film before Treatment

appeared to be intact in both views There was elevation of the periosteum for about 1 cm

The patient's chart remained normal On the third hospital day an operation was performed

#### DIFFERENTIAL DIAGNOSIS

DR GRANTLEY W TAYLOR An eighteen-year-old girl presented in her arm just above the elbow a mass of eight weeks' duration, which was not tender or painful She had received a course of fifteen x-ray treatments before she came to the hospital, so that presumably a diagnosis had been made I do not know, but I infer that the treatment did not affect the lesion This was essentially a symptomless mass, and the only findings on physical examination that were relevant were the presence of a mass and some skin changes in the vicinity, which I should say were probably attributable to the x-ray treatments she had had The skin in the area was mottled and depigmented The laboratory work was essentially noncontributory The chart was flat and the serum calcium,

Figure 2 X-Ray Film After Treatment

ence by abnormal chemical findings in the blood Reviewing the inflammatory conditions we have osteomyelitis, syphilis, tuberculosis and a few extremely rare diseases We have nothing in the data at present to justify the assumption that any one of these is present, and we are brought to the fact that we are dealing with a tumor

The question arises as to whether this is primary or metastatic tumor, and again we have nothing in the record as presented to give us any cause to suppose we are dealing with metastatic malignancy Of the primary tumors we can be

concerned with a benign or a malignant lesion. To my mind the character of the x-ray film as shown here in no way suggests a benign lesion. The defect is very irregular. Around its margins there is nothing suggesting the lobulations of a chondroma. I think that we are entitled to rule out chondroma or osteoma, giant-cell tumor, and so forth, on the basis of this x-ray appearance, and we are brought to the conclusion that we are dealing with a malignant tumor. I do not believe that we are justified in limiting ourselves wholly to a Ewing's tumor and to osteogenic sarcoma in this differential diagnosis. Parker and Jackson\* have recently described reticulum-cell sarcoma as a tumor of bone.

Are there other tumors to which we need to give thought? When I read this description I could not be sure that we were not dealing with a lesion like a single myeloma, which sometimes occurs and presents a confusing picture. However, this lesion is so clearly cortical that I do not believe we can relate it in any way to a disease which is primary in the bone marrow.

The reaction to x-ray treatments is of a good deal of interest. I wonder whether we can say that this ring of bone reaction outside the tumor might have been present originally but that through some technical error in the way the film was taken it failed to show up, I do not picture that type of reaction as an immediate consequence to a series of x-ray treatments. This film shows a rather narrow ring of periosteal bone, with a vague hint of trabeculation on its inner border, and to my mind it raises the question of some sort of bone cyst. I do not know of any sort of bone cyst which would develop in the periosteum in that fashion. I think if we were dealing with a subperiosteal chronic osteomyelitis we should have more suggestion of reactive new bone on the side of the shaft. If we had such a reaction this picture would be consistent with chronic inflammation. The margins of the defect certainly are very ragged in the original film, and in this one quite smooth, which indicates that there has been a distinct effect on the pathologic process as a result of the x-ray and a tendency for bone repair to take place. Now what sort of tumor will respond to fairly extensive x-ray treatment—Dr Hampton tells me the total dose was about 4000 r. Conspicuously, a Ewing's tumor responds very well to radiation treatment, as does a myeloma or a reticulum-cell sarcoma. However, the x-ray appearance rules out myeloma. I believe that either a reticulum-cell sarcoma or a Ewing's tumor would be perfectly consistent with all the information

that we have in this case. I should like to have Dr Holmes present his views of the x-rays.

DR. GEORGE W. HOLMES: I know the answer. However, I think it might be interesting if I reviewed my own reaction to this case.

I first heard of this patient through a letter and films from a doctor in Vermont who had the case originally. I had the history about as it has been given and this set of films, with the statement that the patient's parents had refused operation. They would permit a biopsy, but the doctor very wisely refused to do it without permission to operate, so he sent the films to me with the question as to whether she ought to have x-ray treatment. I said at that time, reasoning very much as Dr Taylor did up to that point, that it could not be a benign tumor and probably was malignant. The patient's other bones were x-rayed and carefully studied for the possibility of a metastatic lesion. I finally came down to the only seemingly possible diagnosis—a primary malignant lesion of bone. I thought treatment was justified so he went ahead and treated her. Then after the treatment was completed they sent her down for a consultation because the family was getting anxious. Dr Simmons and I saw her, and we could not explain the x-ray picture taken at that time on the basis of x-ray effect. My impression was that the separation of the periosteum from the shaft did not develop during the interval but merely became visible and that the separation of periosteum from shaft was present but not visible at the time of the first examination. I doubt if the deposit of calcium had anything to do with the x-ray treatment, it is the natural course of events with separation of the periosteum.

DR. TAYLOR: Do you believe that the tendency of the shaft side to smooth itself was attributable to the same reaction?

DR. HOLMES: I think that the irregularity was due to the same thing that separated the periosteum from the shaft.

DR. TAYLOR: In the first film it looks rougher than in the others.

DR. HOLMES: I agree.

DR. TAYLOR: What I have been attributing to the result of x-ray treatment is apparently only attributable to the passage of time. What would give rise to the elevation of periosteum—which must have taken place at the time of the original plates—so recently as not to have shown reaction? Is trauma a possible explanation? She was injured in the hurricane, but so far as I can make out the head and the legs suffered whereas the rest of the body did not. Perhaps she had been so confused with the bump on the head that she was

\*Parker F. Jr., and Jackson H. Jr.: Primary reticulum cell sarcoma of bone. *Surg. Gynec. & Obst.* 63:45-53, 1937.

not aware of an injury of the arm. Could a subperiosteal hemorrhage account for the picture? I still do not believe that the shaft should be as irregular as it appears to be from subperiosteal hemorrhage. I am completely at a loss in the matter of making a diagnosis. I still have the impression that perhaps it was a malignant bone tumor, such as a Ewing's tumor, but I say this without any great confidence.

DR. TRACY B. MALLORY: I think that Dr. Taylor has shown wisdom in not committing himself to a definite diagnosis.

DR. CHANNING C. SIMMONS: I might add that this girl was seen by an eminent orthopedic surgeon in this city and one in New York, both of whom made a diagnosis of malignant tumor and advised against operation because they believed it to be incurable. Dr. Ernest A. Codman saw these films and thought it was probably a benign tumor, actual type unknown. He agreed that it might be malignant. I thought it was probably a malignant tumor, type unknown, but did not dismiss the possibility of its being benign. That is as far as anyone got. Since then I have seen a paper describing subperiosteal bone cysts in von Recklinghausen's disease. So far as I could determine she had no evidence of subcutaneous nodules, pigmented areas in the skin or other forms of that disease.

DR. MALLORY: Will you describe your operative findings?

DR. SIMMONS: At operation a subperiosteal cyst containing clear brown fluid was found. The outer wall was composed of fibrous tissue and periosteum with areas of calcification and the inner wall of normal appearing cortical bone. The entire outer wall of the cyst was removed, allowing the muscle to come in contact with the normal appearing bone.

#### CLINICAL DIAGNOSIS

Sarcoma, right humerus?

Benign bone tumor, right humerus?

#### DR. TAYLOR'S DIAGNOSIS

Ewing's tumor, right humerus?

#### ANATOMICAL DIAGNOSIS

Bone cyst, etiology undetermined

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: The microscopic examination of the wall of the cyst showed fibrous tissue and a moderate number of foreign-body giant cells, with no evidence of neoplasm, so that the diagnosis remains bone cyst, etiology unknown.

DR. TAYLOR: Is this a possible sequela to trauma with hematoma?

DR. SIMMONS: May I answer that? This girl was injured in the hurricane. A chimney fell through the roof injuring her, killing two other girls and breaking the back of a third one. The doctor who examined her carefully the following day assured me that there was no abrasion on the arm and that she found the tumor at that time.

A PHYSICIAN: Did the x-ray treatment have any effect?

DR. SIMMONS: None at all. Presumably that was done at the psychological moment after the acute reaction had subsided and before the secondary fibrotic changes had taken place.

A PHYSICIAN: Was the wall of the cyst enucleated?

DR. SIMMONS: No, there was no capsule. The outer wall was composed of periosteum with bone in it.

DR. AUBREY O. HAMPTON: The thing I object to is accepting a pathologist's diagnosis in regard to something that is past. How does he know what was here first?

DR. MALLORY: I have not the slightest evidence to offer. I can only guess, as you can.

DR. HAMPTON: It is certainly conceivable that something, perhaps a neoplasm, that had been there was completely destroyed by radiation. The pathologist cannot tell what may have been there before the radiation.

DR. TAYLOR: Do you want to offer a suggestion as to what was there?

DR. HAMPTON: I do not.

DR. MALLORY: I believe this girl is going to remain well.

## CONVALESCENCE

CONVALESCENT care is relatively neglected in the United States. Its importance in the restoration of health does not seem to be properly appreciated by physicians, otherwise there would be greater demand for facilities to care for convalescent patients.

Several pleas have been made in the past that more interest be taken in convalescence, but relatively little progress has been made. A new challenge is at hand—a report of a study of convalescence undertaken by an Advisory Committee on Convalescence of the Boston Council of Social Agencies under the leadership of Miss Ida M. Cannon.<sup>1</sup> In this report it is estimated that 12,000 patients from the wards and outpatient departments of Boston hospitals need convalescent care

annually, but in 1937 only 2500 were known to have received it, and a large proportion of these were children for whom facilities are far more adequate than those for adults. There are only three chartered institutions for adult convalescent care in Boston, with a total of 96 beds, of these only 10 are for men and all are for ambulatory patients. In spite of these small facilities none of the institutions are used to full capacity. Although several factors are involved, the chief reason for this seems to be that the profession is not sufficiently interested in convalescence. For economic and emotional reasons a patient is apt to resist a suggestion that two or three weeks be spent at a convalescent home, so that the demand for beds for convalescent patients must be created by the physician. Yet convalescence is not a very interesting subject to the average doctor, and often is given little consideration by those in charge of patients in large hospitals—a group of individuals who particularly need institutional convalescent care.

Undoubtedly fatigue, in one form or another, is a major symptom of a large number of individuals. The role played by so-called mental or physical fatigue, and by altered physiologic states that cause individuals to note they feel fatigued, in the development of disease is not well understood, but undoubtedly fatigue greatly influences the onset and the intensification of many disorders of man. A significant amount of illness could probably be prevented by a proper appreciation of the danger signal—fatigue—and by intensively treating individuals who complain of it. This can often be done successfully in places designed for convalescent patients and especially when the patient's home is unsuitable for the purpose.

The contrast between facilities for convalescent individuals in Great Britain and the United States is indeed striking.<sup>2</sup> In Great Britain there existed, in 1935, 431 homes for convalescent care as against 179 in the United States chartered as such. In Great Britain they are widely distributed, whereas here there are twenty-four states without any facilities, and 50 per cent of the beds are near

A significant amount of illness could probably be prevented by a proper appreciation of the danger signal—fatigue—and by intensively treating individuals who complain of it. This can often be done successfully in places designed for convalescent patients and especially when the patient's home is unsuitable for the purpose.

The contrast between facilities for convalescent individuals in Great Britain and the United States is indeed striking.<sup>2</sup> In Great Britain there existed, in 1935, 431 homes for convalescent care as against 179 in the United States chartered as such. In Great Britain they are widely distributed, whereas here there are twenty-four states without any facilities, and 50 per cent of the beds are near

New York City The British homes are used to capacity, 252,000 people receiving care in a year, and during the depression the facilities were uncurtailed, indicating the importance with which they are regarded In Boston the institutions for convalescent patients connected with three large hospitals have been closed, chiefly for reasons of economy But would it not be possible that much expense to a general hospital could be saved by transferring many patients to a department for convalescent care before they are well enough to be sent home but after they are past the acute phase of illness? At the present time many recumbent convalescent patients are being cared for in nursing homes—some good, some poor, but all unlicensed and unsupervised

A committee of the Hospital Council of Boston has just been established to study the recommendations of Miss Cannon's committee It is to be hoped that a program for the meticulous care of patients during convalescence will be forthcoming

### A COMMENDABLE PLAN

AMONG the many sociologic and economic programs under way and in contemplation throughout this country those pertaining to medical service are being studied and operated under a great variety of plans This situation has come about because of an awakened appreciation of the importance of utilizing all useful devices and agencies which may promote the efficiency of scientific medicine

While differences of opinion respecting some of the plans exist, there is a common belief that every community should have the resources of a hospital available for such cases as may need extra-domiciliary treatment This applies to a large pro-

portion of accidents, to surgical operations and to facilities for diagnosis and certain highly specialized forms of treatment Medicine today is, in many ways, a science depending on the services of qualified technicians with elaborate chemical and mechanical facilities at hand for the diagnostician, be he either surgeon or internist

With this understanding, hospitals have been built in comparatively small municipalities and, when well administered, have been blessings for such communities These hospitals are rarely self supporting and have been maintained by endowments or contributions of public-spirited citizens Present financial conditions warrant the fear that the small community voluntary hospital will not be able to meet the requirements of advancing scientific medicine and that the growing proportion of well-educated doctors will not be satisfied with hospital facilities below the standards to which they have been accustomed in their intern days

It is desirable to keep these small hospitals well above the grade of nursing homes A step in the right direction is the agreement recently put into effect by the Salem Hospital and the Mary Alley Hospital in Marblehead, whereby the equipment and facilities of the larger institution are made available for the hospital and physician of the smaller community

This plan seems to be a feasible solution of the problems confronting the small hospitals, for it makes possible a service practically identical with that of an institution prepared to meet almost all the demands imposed on or incident to the practice of scientific medicine Probably a survey throughout Massachusetts and other states will disclose communities with conditions similar to those in Salem and Marblehead, where the plan outlined might be advantageously adopted

We congratulate these two communities for their evidence of a broad-minded spirit of collaboration which will, we believe, be a pattern for similar experiments

## POSTPARTUM HEMORRHAGE

Mrs. M. M., a twenty-nine-year-old primipara at term, entered the hospital early in the morning of February 5, 1925, the membranes having ruptured.

Her family history was noncontributory. The patient gave a history of Vincent's angina, measles and influenza. She had had no operations. Catamenia began at twelve, were regular with a twenty-eight-day cycle and lasted four to five days, with little pain. Her last period was April 28, 1924, making her due for confinement February 1.

She was first seen on June 20, 1924, at which time her heart was rapid but there were no murmurs. Her lungs were clear and resonant, there were no rales. Her blood pressure was 136 systolic, 64 diastolic. A vaginal examination showed the cervix deep in the vagina and soft. The uterus was anterior. Her pregnancy progressed normally until the date of entry.

The patient continued to lose a little amniotic fluid all February 5 and started in indefinite labor about midnight. At 9 a. m. on February 6 the contractions were beginning to come regularly about every three minutes. Examination showed the cervix dilated to admit two fingers and thin, and the head well in the pelvis. At 11 a. m. the cervix was dilated to admit four fingers. At 1 p. m. a forceps was applied to a rotated ODP, after a median episiotomy because of the lack of progress. A male child in excellent condition and weighing 8½ pounds was delivered. The placenta apparently separated immediately but was not extruded. The fundus was not held properly, and a half hour after delivery it was well above the umbilicus. After the placenta, with membranes complete, was delivered intact, by the Credé method, a clot the size of a baby's head followed. Oxytocics were administered, but the uterus did not contract until the pulse had risen to 160 and the blood pressure had dropped to 90 systolic. The patient was transfused with 450 cc of citrated blood taken from a compatible donor. She made an uneventful convalescence and was dis-

charged from the hospital eighteen days after delivery.

*Comment.* There is no explanation for the atony that accompanied this delivery except that the fundus was not held properly after delivery. If it had been, it would have been appreciated that the uterus was rising and one would have known that it was filling with blood. Then the placenta might have been delivered before so much blood had been lost. This uterus was not explored because oxytocics and transfusion eventually effected normal contraction. It has been found in many of these cases of hemorrhage that transfusion not only quickly replaces the lost blood but stimulates the uterine muscles to contract.

MEDICAL POSTGRADUATE  
EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning February 20.

## BRISTOL NORTH

Thursday, February 23, at 4 00 p. m., at the Morton Hospital, Taunton. Subject—Heart Disease. The treatment of 'heart attacks or cardiovascular emergencies.' Instructor: Sylvester McGinn Lester E. Butler, *Chairman*.

## BRISTOL SOUTH (Fall River Section)

Tuesday, February 21, at 4 00 p. m., at the Union Hospital, Fall River. Subject—Medical Complications in Pregnancy. Instructor: James C. Janney. Howard P. Sawyer, *Chairman*.

## MIDDLESEX EAST

Tuesday, February 21, at 4 00 p. m., at the Melrose Hospital (Colby Hall), Melrose. Subject—The Indications and Contraindications for Removal of Tonsils and Adenoids. Instructor: Edwin T. Wyman. Walter H. Flanders, *Chairman*.

## MIDDLESEX NORTH

Thursday, February 23, at 4 30 p. m., at St. John's Hospital, Lowell. Subject—Syphilis. Latent syphilis—diagnosis and treatment. Instructor: Rudolph Jacoby. William S. Lawler, *Chairman*.

## HEART DISEASE VERSUS HEART FAILURE\*

The title of this talk, Heart Disease versus Heart Failure, was chosen in order to point out that heart disease does not necessarily imply heart failure. The term heart disease signifies that some of the working parts of the heart have been damaged, while heart failure signifies that the heart is unable to do its job as it should be done.

The fact that a person has a structural deformity of his heart does not necessarily signify that he is seriously sick or that his life is in danger. Much of the important work

\* A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

\* A Green Lights to Health broadcast given by Dr. Herriman L. Blumgart on Wednesday, January 18, and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

in the world is accomplished by people with heart disease. To use the example of the automobile, there may be knocks and squeaks in the engine, but used carefully and skillfully, it may provide entirely adequate service to its owner for many years and may actually survive many more smoothly running engines recklessly run and abused. Every physician sees numerous individuals who are heart cripples, not because of a structural deformity of the heart, but because fear and anxiety have paralyzed the patient. Such patients would lead happy and useful lives if they knew how many individuals beyond seventy show evidences of heart disease which have been present but caused no trouble for thirty, forty or even fifty years. As Osler remarked "The way to live forever is to acquire a chronic disease and take care of it.

Of the infections which damage the heart, the worst enemies are rheumatic fever, syphilis and occasionally certain acute infections such as diphtheria, scarlet fever, tonsillitis, pneumonia and gonorrhea. The natural wear and tear of old age, which in present-day life frequently occurs before it should in the middle years, causes hardening and narrowing of the arteries which supply the heart with blood. This leads to weakness or even failure of the muscular power of this organ. Of the various infectious diseases, rheumatic fever is first in importance. Most frequently it afflicts children, usually after the age of five, and young adults. This disease often comes on with tonsillitis, and there are likely to be migrating pains in the joints and muscles, wrongly called growing pains, and sometimes redness, tenderness and swelling of various joints, nosebleeds, fever and malnutrition. This infection may cause weakening of the heart muscle and may permanently scar and distort the valves of the heart. In middle adult life we find not only those who have suffered from rheumatic fever, but those who, having had syphilis in earlier years, have felt so well that they have disregarded treatment of the disease, or may not even have known that they had syphilis. During the years of neglect, the infection may silently cause destruction of the root of the large vessel leading from the left pumping chamber and of the heart valve lying very near it. The individual may feel perfectly well for many years until he suddenly becomes aware of symptoms such as loss of breath, pain, palpitation and weakness. The treatment of such patients is discouragingly unsatisfactory, compared to the striking curative value of modern remedies in the early stages of the disease.

Pain may be an important warning sign of disease of the heart. Not infrequently, however, the patient may describe his symptoms as a vague sense of oppression below the breast bone or as a dull, heavy sensation in the shoulders or arms brought on by exertion, emotion, overeating or exposure to cold. One should remember, however, that other organs such as the skin, muscles, ribs and lungs are also situated within the chest and may give rise to similar deceiving symptoms even when there is no real heart disease. Pain in these places may also be due to irritation of nerves or even to diseases of the stomach and gall bladder. On the other hand, symptoms arising in the heart may be felt only in a distant area such as the fingers, the shoulders or the upper part of the abdomen, or may give rise to belching or burning sensations. In any event, such symptoms, particularly when they occur in people of middle age, should make a person consult his physician, for not only may heart disease be suggested by symptoms in other parts of the body, but diseases elsewhere may be discovered because of sensations felt in the region of the heart.

The causes of cardiac pain are numerous, but almost all have to do with interference with the blood supply to the

heart muscle. With hardening and narrowing of the arteries of the heart, the amount of blood which can be pumped through these vessels may be enough while a person is resting, though not enough to take care of the increased amount of work the heart is forced to do during exercise or emotion. The appearance of such pain should be regarded by the patient as a red light or danger signal which, if heeded, will prevent an accident, but which, if neglected, may lead to disaster. People who take care not to work too hard or get excited, which may bring on such attacks, and who can lead a quiet, peaceful life, often live for many decades. Sometimes one of the arteries may be completely blocked and give rise to severe, crushing pressure or pain. The heart muscle supplied by such a vessel then degenerates. Even then, after a part of the heart is out of commission, the rest of the heart may be able to take on the job of the injured part, and people have been known to live comfortably for twenty or thirty years after a heart accident of this sort.

Many people with heart disease who try to live more strenuously than is wise for the condition of their hearts have signs of heart failure. The inability of the heart to pump a sufficient amount of blood in a forward direction causes a backing up of blood in the veins and then congestion of the various organs, skin and underlying tissue takes place. Breathlessness, chronic cough with whitish or pinkish sputum, congestion of the liver, giving rise to pain in the upper right portion of the abdomen, swelling of the legs and inability to lie flat in bed are frequently due to heart weakness. By giving the heart sufficient rest, being quiet in bed, and by the skillful use of drugs made possible by the extraordinary advances in scientific medical knowledge, these signs of failure usually disappear. Such people may lead full, happy and successful lives, particularly by giving the heart less work to do, by cutting down bodily activity, by getting enough sleep and rest, by a slowing down of pulse and by loss of weight. Taking digitalis and certain other drugs which remove the accumulations of fluid is an important aid in treatment. Extraordinary advances have also been made in the treatment of heart disease by means of surgery. In spite of the fact that the heart is very sensitive to injury and is situated within the bony cage of the chest, removal of accumulations of fluid surrounding the heart can be accomplished with safety. In certain forms of heart disease the heart becomes surrounded by a tough fibrous sac which interferes with normal pumping. Surgeons are now able to enter the chest and release the heart from this tight, almost bony, envelope. The injection of nerves by alcohol to relieve the pain of what is called angina pectoris and the removal of the thyroid gland to lessen the work of the heart are other surgical procedures by which increased comfort and long life may be provided for certain cases.

\* \* \*

Q Does the occurrence of a very rapid pulse or palpitation suggest the presence of heart disease?

A Palpitation, one of the commonest symptoms of heart disease, means a consciousness of the heart beat. Palpitation due to increased rate of contraction may be caused by disease elsewhere, such as too much action of the thyroid gland. This symptom, of course, also comes on in health, with emotion or strenuous exercise, or even on lying down in bed on the left side in the quiet of the night. Some people have occasional extra beats of the heart throughout their life, feeling a skipping of the heart. This irregularity is due to the play of nervous impulses, and some people have noticed this from early life to a ripe old age, without its causing any further difficul

ty Occasionally, however, and particularly when this irregularity of the heart beat appears for the first time in middle life, it may be a warning sign of some structural abnormality or an increased irritability due, perhaps, to excessive smoking. Another sign of the nervous heart may be paroxysms of rapid heart action. The individual, without warning, suddenly experiences an extraordinary pounding of the heart which may last for minutes, hours or even days. Such attacks, which are most disconcerting, are not dangerous and fortunately the physician has effective remedies with which to stop and to prevent them. It is a great tribute to the heart that in spite of such overwork it does not wear out during such an attack or suffer any lasting damage. Nevertheless, people should not disregard such disorders of the heart beat, but rather allow a physician to investigate and explain what they mean.

Q If a patient has heart disease, what can be done to prevent heart failure?

A. Once heart disease has come on, there is often a considerable period of time before it produces any important interference with the function of the heart. During this period in which there are no symptoms, the problem of the physician and the patient is to prolong this period of perfect well-being and prevent the onset of heart failure. To do this, the physician attempts not only to control the original causes of heart disease but also to treat other conditions which, while not enough in themselves to cause heart failure, may bring about heart failure in an already diseased heart. These conditions include acute infections, overwork, emotional strain, obesity, too little or improper food, anemia, pregnancy and thyroid disease.

Q Is it bad to be fat if you have heart disease?

A The longer the belt line, the shorter the life line. High blood pressure is over two and a half times as common among the overweights as among those of average weight, and the death rate from heart disease and cerebral hemorrhage is one and a half times that of those with normal weight and nearly twice that of underweights.

For angina pectoris the difference is even larger. The mortality of overweights from this condition is more than twice that of those with average weights and two and a half times that of underweights. It is clear then that great gains in individual and community health could be brought about if we could cut down the number of fat people.

Q Has any progress been made in the prevention of heart disease?

A. While great advances have been made in the diagnosis and treatment of heart disease, even more important progress has been made in regard to the prevention of heart disease. Diphtheria, once so prevalent, is now successfully controlled. The causative agent of rheumatic fever is unknown, but it is recognized that overcrowded living conditions, poor nutrition and neglected infections, particularly of the teeth and tonsils, make children more likely to have rheumatic fever. The rising standards of living and more adequate medical care have led to a real lessening in the number of cases of rheumatic heart disease.

The scientific advances in medicine are nowhere better seen than in our knowledge of syphilis. The infecting organism has been discovered, the different ways by which the disease is passed on are recognized, the clinical manifestations of the disease are accurately known, exact diagnostic tests are available, and effective methods of treatment have been worked out. This information, together with the present public health campaign, should lead to a great reduction in syphilitic heart disease.

Q Is heart disease increasing?

A. In spite of such progress, an alarming increase in the occurrence of heart disease has been reported by many observers. There are today probably over two million people in this country suffering from some type of heart disease, and statistics seem to show that the death of one of every seven of us will be caused by disability of the heart. Heart disease as the cause of death is more frequent than cancer, pneumonia and tuberculosis combined.

Q Is this increase of heart disease something to worry about?

A. Careful study of these statistics is reassuring, however, rather than, as is usually thought, a ground for serious worry. Great progress has been made in the prevention and treatment of tuberculosis and the treatment of diabetes and the diseases of infancy and childhood. The effective control of these diseases, improved sanitation and other successful public health measures have led even during the past twenty five years to an increased life expectancy of fifteen years. Many people who formerly died of diabetes or died from one of the infectious diseases of childhood attain old age with its tendency toward hardening of the arteries and consequent heart disease. The increase in heart disease is therefore due to the fact that heart disease is mainly a disease of the older years and that over 60 per cent of all deaths now occur after the age of forty five.

Q What is coronary thrombosis?

A. Coronary thrombosis is a condition in which one of the arteries which supplies the heart with blood becomes plugged with a firm clot of blood.

Q Can anything be done to prevent the accident of coronary thrombosis?

A. If people find that they have to cut down on exercise, if they have attacks of pain in their chest and shortness of breath, then they should be kept very quiet so that, if a clot of blood occurs, nature will have a chance to form other blood vessels to take the place of the plugged one. Avoid strenuous physical effort and emotional excitement which, with its attendant increased blood pressure, leads to a greatly increased strain on the heart.

Q Does physical activity immediately after severe pain affect the amount of damage to the heart muscle?

A. Our latest knowledge indicates that it certainly does. Tying off a blood vessel in dogs causes a larger area of damage in those which are allowed to exercise afterward than it does in those which are kept quiet. Exercising muscle (and the heart is a muscle) requires more oxygen and therefore a larger blood supply than a resting one. This is in keeping with the accumulated experience of doctors.

If every patient suddenly stricken with severe crushing pain were to lie down, there would probably be a decrease in the number of deaths from the disease. If patients followed their doctor's advice and remained at absolute rest in bed for a sufficient time, some deaths and much in capacity would be avoided.

Q What is the length of time a patient should stay in bed?

A. Healing time is variable—let us say three to eight weeks. Mental and physical rest speeds up the healing process. Eating increases the work of the heart by 50 per cent, and therefore the diet should be light and the patient, if fat, should lose weight.

\* \* \*

Don't worry about heart disease, but if you think you have it, see your doctor and let him tell you what to do, which may very likely be, to stop worrying.

## DEATHS

OSGOOD—GEORGE E OSGOOD, M.D., of St. Petersburg, Florida, died September 21, 1938. He was in his seventy sixth year.

Dr Osgood received his degree from Harvard Medical School in 1887. He was a fellow of the American Medical Association and the Massachusetts Medical Society.

WHITE—WILLIAM A WHITE, M.D., of 249 Warren Street, Roxbury, died February 6. He was in his seventy-first year.

Born in Weare, New Hampshire, he received his degree from Tufts College Medical School in 1894. In 1910 he joined the staff of the Massachusetts Women's Hospital, Roxbury, and was on the staff at the time of his death. Dr White was a former instructor in the history and practice of medicine and lecturer on diseases of children at Tufts College Medical School. He was also professor of materia medica at the Boston Dental College.

His memberships included the Massachusetts Medical Society, the American Medical Association and the Boston Medical Library.

A son, Dr William A. White, Jr., two daughters, a sister and four grandchildren survive him.

## MISCELLANY

RÉSUMÉ OF COMMUNICABLE DISEASES  
IN MASSACHUSETTS FOR DECEMBER, 1938

DISEASES	DEC 1938	DEC 1937	FIVE YEAR AVERAGE*
Anterior poliomyelitis	0	1	5
Chickenpox	1096	1670	1482
Diphtheria	23	18	50
Dog bite	561	570	463
Dysentery, bacillary	14	19	4
German measles	55	72	117
Gonorrhea	400	495	556
Lobar pneumonia	415	411	512
Measles	907	349	1148
Meningococcus meningitis	5	4	8
Mumps	470	298	562
Paratyphoid B fever	6	4	1
Scarlet fever	507	926	836
Syphilis	480	475	422
Tuberculosis pulmonary	177	341	269
Tuberculosis other forms	23	47	29
Typhoid fever	3	10	11
Undulant fever	5	8	4
Whooping cough	784	732	911

\*Based on figures for preceding five years.

## RARE DISEASES

*Actinomyces* was reported from Boston, 1, Southbridge, 1, total, 2.

*Diphtheria* was reported from Boston, 1, Cambridge, 2, Danvers, 1, Lawrence, 8, Northbridge, 1, Oxford, 1, Plymouth, 1, Salem, 1, Stoneham, 1, Worcester, 6, total, 23.

*Dysentery, bacillary* was reported from Fall River, 5, Northampton, 1, Somerville, 1, Wellesley, 7, total, 14.

*Infectious encephalitis* was reported from Boston, 2, Lawrence, 1, Marlboro, 1, Milton, 1, Walpole, 1, Waltham, 1, total, 7.

*Malaria* was reported from Foxboro, 2, Springfield, 1, total, 3.

*Meningococcus meningitis* was reported from Charlton, 1, Millbury, 1, Newburyport, 1, Rutland, 1, Worcester, 1, total, 5.

*Paratyphoid B fever* was reported from Cummington, 1, Framingham, 1, Saugus, 1, Springfield, 3, total, 6.

*Pellagra* was reported from Gardner, 1, total, 1.  
*Septic sore throat* was reported from Amesbury, 3, Boston, 3, Cambridge, 1, Haverhill, 1, Lawrence, 2, Marshfield, 2, Sturbridge, 1, total, 13.

*Trachoma* was reported from Boston, 1, total, 1.

*Trichinosis* was reported from Boston, 3, total, 3.

*Typhoid fever* was reported from Boston, 1, Foxboro, 1, Kingston, 1, total, 3.

*Undulant fever* was reported from Boston, 1, Gardner, 1, Lynn, 1, Marlboro, 1, Worcester, 1, total, 5.

For the second time, the first having occurred in December, 1936, not a single case of anterior poliomyelitis was reported. The total incidence for the year 1938 was the lowest ever recorded in Massachusetts.

Chickenpox, measles, German measles, and diphtheria were reported below the five-year average. Except for 1918, scarlet fever showed record low incidence.

Pulmonary tuberculosis was reported at a record low figure. Lobar pneumonia, whooping cough, mumps, tuberculosis (other forms) and meningococcus meningitis were reported below the five year average. Typhoid fever showed record low incidence. For the second consecutive month, paratyphoid B fever was reported at a record high figure.

Animal rabies showed record low incidence. A previously noted focus in Grafton was still active.

## NOTES

At the recent meeting of the History of Science Society held in Chicago, Dr. Henry R. Viets, of Boston, was elected secretary treasurer.

At a recent meeting of the alumni of Boston University School of Medicine, the principal guest speaker was Dr. Morris Fishbein, editor of the *Journal of the American Medical Association*. Dr. Fishbein stressed the importance of the general practitioner to the medical care of the populace and stated that 85 per cent of sickness is still cared for by the family doctor in his office or in the patients' homes. He complimented the work of the Boston University School of Medicine in developing well trained general practitioners and in keeping them well informed.

Dr. Hans Mautner, formerly of Vienna, has recently accepted a full time teaching position as professor of pharmacology in the Middlesex University School of Medicine. He received his M.D. degree from the University of Vienna in 1909, and has devoted twenty seven years to research at the Pharmacological Institute of the University of Vienna, as a co-worker of Drs. H. H. Meyer and E. P. Pick. Dr. Mautner had been vice president of the Association of the Vienna Physicians for the past ten years, and had also served as chairman of the Vienna Society of Children's Diseases and was a member of the Board of the Vienna Biological Society and chief of the dispensary for children of the Vienna Herzstation.

The following appointments at Harvard Medical School and Harvard School of Public Health were recently announced: William W. Sargent, of Boston, research fellow in psychiatry, D.P.M. England '36; Charles L. Fox, Jr., of Boston, research fellow in bacteriology, M.D. Long Island 34; Albert M. Moloney, of Boston, assistant in roentgenology, M.D. Tufts '25; James S. Mansfield, of Boston, assistant in medicine, M.D. Harvard 32; Chia Tung Teng of Boston, research fellow in medicine, M.D. Peking Union 33; William M. Hammon, of Brookline, instructor in epidemiology, M.P.H. Harvard '38.

## CORRESPONDENCE

## TREATMENT OF CHRONIC ALCOHOLISM

*To the Editor* I was interested in reading Dr. Bloomberg's article, "The Treatment of Chronic Alcoholism with Amphetamine (Benzedrine) Sulfate," as I had carried on a somewhat similar experiment fifteen or twenty years ago.

I have either mislaid or destroyed my notes, but I suggested buttermilk as a substitute for alcohol in a series of fifty male patients. Only a small percentage reported with any accuracy, but the results in this small group were quite similar to Dr. Bloomberg's findings.

I reached the conclusion that the best results were obtained in those who took my advice most seriously. In other words, psychotherapy rather than buttermilk deserved the credit.

Brookline, Massachusetts

## ARTICLES ACCEPTED BY THE AMERICAN MEDICAL ASSOCIATION COUNCIL ON PHARMACY AND CHEMISTRY

*To the Editor* In addition to the articles enumerated in our letter of December 16 the following have been accepted:

Abbott Laboratories

Solution of Epinephrine Hydrochloride 1:1000, 1 fl. oz. bottle

Solution of Epinephrine Hydrochloride 1:1000, 1 cc. ampule

Thiamin Chloride Abbott

Tablets Thiamin Chloride Abbott, 0.33 mg

Tablets Thiamin Chloride Abbott, 10 mg

Tablets Thiamin Chloride Abbott, 3.3 mg

Ampules Thiamin Chloride Abbott, 666 mg

Iodeikon Emulsion Powder Abbott

Ampules Estrone, 0.5 mg in Oil, 1 cc

Pentothal Sodium Abbott

Ampules Pentothal 10 gm (15½ gr), buffered with sodium carbonate 0.6 gm

Ampules Pentothal 0.5 gm (7½ gr), buffered with sodium carbonate 0.3 gm

Lederle Laboratories

Solution Epinephrine Hydrochloride 1:1000, 1 fl. oz. bottle

Solution Epinephrine Hydrochloride 1:1000, 1 cc. ampule

Solution Epinephrine Hydrochloride 1:1000, 5 cc. vial

Eli Lilly & Company

Tuberculin Ointment (Wolff) Lilly

The Maltbie Chemical Company

Ampules Caffeine with Sodium Benzoate, 0.5 gm. (7½ gr), 2 cc.

Ampules Sodium Thiosulfate Maltbie, 10 cc.

The Upjohn Company

Hypodermic Tablets Strophanthin 0.00033 gm. (1/200 gr)

Hypodermic Tablets Digitalin 0.00065 gm (1/100 gr)

U.S. Standard Products Company

Solution Epinephrine Hydrochloride 1:1000, 1 fl. oz. bottle

Solution Epinephrine Hydrochloride 1:1000, 1 cc. ampule

Chicago, Illinois

## REPORTS OF MEETINGS

## BOSTON PATHOLOGICAL SOCIETY

The Boston Pathological Society met at the Evans Memorial Hospital on Thursday evening, November 17, for a symposium on the recent equine encephalitis epidemic. Dr. Charles F. Branch presided.

Dr. Allen Hill reported concerning 8 cases observed at the Children's Hospital, in which the ages of the patients, with the exception of a fourteen-year-old boy, ranged between one and eighteen months. The cases were in three groups: 2 patients who came in violently ill and died within twenty-four hours before a diagnosis could be made—in both cases the diagnosis was established by postmortem examination and the isolation of the virus; 3 patients who also came in critically ill but remained in this condition for five to twenty-one days before dying; and 3 patients who managed to survive the acute illness but were left with severe residual paralysis.

An example of the first group is the case of a fourteen-year-old boy who, after a morning of normal active play, went to lunch with a slight headache. About an hour later he could not be aroused from his afternoon nap, and he was taken to an outlying hospital. Following a period of drowsy arousal he lapsed back into coma. The next day the spinal fluid contained 30 cells per cubic millimeter and gave a positive Pandy test, so he was transferred to the Children's Hospital. On arrival there, thirty-six hours after onset, the child was rigid, with arms flexed tightly across his chest, and responded to nothing. Lumbar puncture showed 2000 cells, 80 per cent of which were polymorphonuclears. There were no red cells or bacteria, and both aerobic and anaerobic cultures were negative. There were no localizing neurologic signs, and the child grew worse, with convulsions and increasing spasticity despite large quantities of paraldehyde and luminal. The temperature rose to 108 F, and the child died twelve hours after admission in a convulsion.

An example of the third group is the case of a twelve-month-old boy who returned from a normal day at the beach and seemed unusually irritable at supper. He played through the evening in his usual manner—despite a

## REPORTS OF MEETINGS

## BOSTON PATHOLOGICAL SOCIETY

The Boston Pathological Society met at the Evans Memorial Hospital on Thursday evening, November 17, for a symposium on the recent equine encephalitis epidemic. Dr Charles F Branch presided.

Dr Allen Hill reported concerning 8 cases observed at the Children's Hospital, in which the ages of the patients, with the exception of a fourteen-year-old boy, ranged between one and eighteen months. The cases were in three groups: 2 patients who came in violently ill and died within twenty-four hours before a diagnosis could be made—in both cases the diagnosis was established by postmortem examination and the isolation of the virus; 3 patients who also came in critically ill but remained in this condition for five to twenty-one days before dying; and 3 patients who managed to survive the acute illness but were left with severe residual paralysis.

An example of the first group is the case of a fourteen-year-old boy who, after a morning of normal active play, went to lunch with a slight headache. About an hour later he could not be aroused from his afternoon nap, and he was taken to an outlying hospital. Following a period of drowsy arousal he lapsed back into coma. The next day the spinal fluid contained 30 cells per cubic millimeter and gave a positive Pandy test, so he was transferred to the Children's Hospital. On arrival there, thirty-six hours after onset, the child was rigid, with arms flexed tightly across his chest, and responded to nothing. Lumbar puncture showed 2000 cells, 80 per cent of which were polymorphonuclears. There were no red cells or bacteria and both aerobic and anaerobic cultures were negative. There were no localizing neurologic signs, and the child grew worse, with convulsions and increasing spasticity despite large quantities of paraldehyde and luminal. The temperature rose to 108 F, and the child died twelve hours after admission in a convulsion.

An example of the third group is the case of a twelve-month-old boy who returned from a normal day at the beach and seemed unusually irritable at supper. He played through the evening in his usual manner—despite a

momentary twitching of his left arm three hours after supper—and was put to bed apparently normal. Next morning he was found in coma. He had a brief left sided convulsion and despite sedation soon developed two more convulsions. The third convulsion lasted two and a half hours and was still in progress when the child arrived at the Children's Hospital, he was moribund and deeply cyanotic, and the right side was rigid, and the left side relaxed. Two cubic centimeters of intravenous luminal was required to stop the convulsions sufficiently to permit normal respiration. The first lumbar puncture forty-eight hours after onset, showed 246 cells, 45 per cent of which were polymorphonuclears, and the second, six hours later, showed 250 cells with 60 per cent polymorphonuclears. In this child the disease ran a mild and brief course. His temperature, 102°F on admission, promptly climbed to 105°F, where it remained for forty eight hours, while the child was in coma and dependent on parenteral fluids. On the third day the temperature began to drop rapidly and by the fourth day was normal, where it remained. At the end of a week he was able to take feedings, though he remained paralyzed on his right side and showed severe inco-ordination of all movements on the left side. After three weeks with only slight improvement, an encephalogram was done which showed a questionable slight enlargement of the ventricles. At present the child still has a right hemiparesis and inco-ordination of movements on the left side.

All the cases were equally abrupt and violent in onset, and all the patients were as critically ill when they arrived at the hospital twenty four to forty-eight hours after onset. Of the surviving cases, the second patient was in coma for three weeks and remains a pitiable wreck, with generalized spasticity. The third patient is in a cast because of a spastic hemiplegia and is almost completely deaf and apparently blind. One of the patients in the second group ran a temperature between 103 and 106°F for twenty-one days before he succumbed.

All the cases occurred during August and September and were of a violence comparable only to that of overwhelming sepsis or malignant poliomyelitis. All had two or three convulsions before coming to the hospital, and coma was universal. Vomiting, fever, cyanosis, rigidity and bulging fontanelles were almost universal. All had markedly increased intracranial pressure with cell counts ranging from 250 to 2000 cells, 45 to 100 per cent of which were polymorphonuclears. This preponderance of polymorphonuclear cells reversed itself within forty-eight to seventy two hours so that 60 to 100 per cent were mononuclear cells after that time. Fever ranged between 103 and 107°F. Blood leukocytosis was always present, in some cases as high as 40,000 cells with 85 per cent polymorphonuclears. All the cases surviving beyond the first forty-eight hours developed a peculiar edema, with puffy face and limbs, which did not pit on pressure but was brawny and very slow to subside. (In the 2 instances in which the serum protein was determined, it was found to be well above the edema level.) All developed a considerable pallor due to secondary anemia.

For its violence of symptoms and critical course and for its universal outcome of death or hopelessly discouraging residual paralysis, this disease has been one of the most terrifying we have seen. The 5 patients who died showed pathologic changes consistent with equine encephalitis, and the virus was recovered from 3 cases—in 1 as late as seven days after onset.

Discussion brought out that because of the spinal fluid findings on admission which necessitated a differential diagnosis of poliomyelitis and septic meningitis, all cases

were treated with sulfanilamide until negative spinal-fluid cultures were obtained. Spinal fluid sugar and chloride determinations were essentially normal. In no case were red blood cells found in spinal fluid during the early stages.

Dr LeRoy D Fothergill reported on the isolation and identification of the virus. While equine encephalitis due to a virus has been known in Europe for a long time, interest in the disease in this country was first aroused by an epidemic among horses in the San Joaquin Valley in California during 1930-1931. Prompt study isolated the virus and proved its etiologic role. The next problem was the mode of transmission. It was first demonstrated that sick and well animals could be kept together without spread of the disease. In 1933 it was shown that the disease could be transmitted from one animal to another by a mosquito—*Aedes aegypti*. Later, eight varieties of the *Aedes* were found capable of transmitting the disease. Next it was shown that the virus could be recovered from the blood stream of the horse for only a few hours after the onset of the illness and before the temperature rose—thus making the period available for a potentially infective mosquito meal very short. Furthermore it was found that the mosquito could not transmit the disease until four to six days after the blood meal. The reason for this latent period is not known. Once infected the mosquito probably harbors the virus the rest of its life, but it does not transmit the virus to other mosquitoes or its offspring. Later the tick, *Dermacentor andersoni* was found capable of transmitting the disease, of harboring the virus for a long time and of passing it on to offspring in the eggs. The first epidemic in the East broke out simultaneously in the coastal salt marshes on both sides of Chesapeake Bay. A study of this outbreak demonstrated a virus but one which is immunologically distinct from the virus of the disease in the West. The equine disease caused by the Eastern variety is also characterized by a much more severe course and a mortality rate as high as 90 per cent, in comparison with the 25 per cent mortality of the Western type of disease.

In the present epidemic among human beings, the virus was recovered by injecting a suspension of fresh brain intracerebrally into a mouse. After twenty four hours the mouse stops eating, its fur becomes rough, and it later develops convulsions which result in death in forty-eight to seventy two hours. The virus can be recovered from the animal's brain and passed on indefinitely. In this way the virus has been recovered from 8 human cases. As yet it has not been recovered from the blood or spinal fluid. The virus was further identified by protection tests, where in three animals—a normal mouse, a Western-type immune and an Eastern type immune—were injected, only the last mouse survived.

Next came the problem of proving the etiology of the disease in those cases which recovered and that of investigating the possibility of sub-clinical infections, of mild unrecognized cases leaving no residual paralysis and of family contacts. The last is unlikely, because people working with the virus for several years have not developed antibodies. Virus-neutralization tests were used for this study. The results so far have shown that the serums from veterinary and family contacts have no neutralizing power, while that from one of the convalescent cases at the Children's Hospital was able to neutralize 100,000 lethal doses. Discussion brought out that the virus cannot be recovered from the brain of a case in which death is prolonged. Work is being done to discover how early the neutralization test becomes positive. In addition, Dr Roy F Feemster of the Massachusetts Department of Public Health is

trating various parts of the brain to see if the virus has any tendency to localize in special areas.

Dr John Dingle reported on some of the newer epidemiologic features. While adult man is apparently not susceptible to the disease, the mouse, guinea pig, cat, dog, horse and sheep are. For this reason the disease is ideal for laboratory investigations. Some animals can acquire the disease by subcutaneous injection or even feeding of the virus. Soon this was extended to show that most of the common birds, with the exception of the chicken, are susceptible, among them the pigeon. During the past summer, pigeon breeders all along the Atlantic seaboard noticed an unusual number of deaths for no apparent reason. One of these pigeons was studied, and its brain was shown to contain the Eastern strain of equine encephalitis virus. The pigeon deaths all ceased abruptly with the onset of cold weather and coincidental with the end of the equine epidemic. This raises the question of the role of the pigeon as a reservoir or secondary host and may be the explanation of the simultaneous outbreak on both sides of twenty five mile wide Chesapeake Bay.

Discussion brought out that the present epidemic in Massachusetts and northern Rhode Island involved some 200 horses, that the virus from human cases has been passed on in both pigeons and horses, and that calves get only a mild temperature reaction and no severe illness when inoculated, though an encephalitis of cattle is known in Europe and is due to a different virus. The incubation period after inoculation in the human being is unknown but judging from animal experiments is probably between two and five days. The major missing link in the tale, so far, is failure to find mosquitoes or ticks which harbor the virus. But the circumstantial evidence of no contact cases, seasonal incidence and cases separated by several miles is strong, and the statistical probability of finding such insects in the field very slight. Where the disease is harbored during the winter, the natural reservoir and possibility of other intermediate hosts and the possibility of carriers constitute the important unsolved problems.

Dr Sidney Farber presented the pathologic findings and pointed out that much of his work was excellently supplemented and confirmed by that of Dr Charles F. Branch. Grossly the brains showed nothing distinctive aside from considerable edema, with an increase in weight, and an intense congestion most striking in the pons, medulla and basal ganglia. All 5 cases showed a pressure cone.

Microscopically there were four outstanding features (1) Nerve cells throughout the brain showed Nissl substance breakdown, chromatolysis and general cellular dissolution, particularly in the pons, medulla and basal ganglia. Many of the nerve cells were surrounded by polymorphonuclear cells, and some were undergoing phagocytosis. There was also some increase in the number of glial cells. Despite the large numbers of leukocytes no bacteria could be demonstrated by culture or special stains. (2) There were large accumulations of inflammatory cells in the perivascular spaces of Virchow Robin. (3) There was a diffuse meningeal infiltration with inflammatory cells most noticeable about the base of the brain. In 1 case, the changes were striking enough to lead to a diagnosis of basilar meningitis when the brain was first removed. The inflammatory cells in these neurons, perivascular and meningeal infiltrations paralleled the spinal fluid findings at the time of death. During the early stages when most of the cells in the spinal fluid were polymorphonuclear leukocytes, the inflammatory reaction proved to consist chiefly of these cells, and later, when the spinal fluid showed chiefly mononuclear cells the infiltration was chiefly mononuclear. (4) A

striking and widespread arteritis was present with infiltration of the vascular walls by polymorphonuclear leukocytes and a fibrin network. Yet hemorrhages were quite uncommon though a few tiny ones could usually be found.

These lesions were found widespread and most numerous throughout the pons, medulla and basal ganglia. The cortex showed a diffuse but patchy involvement with no normal areas adjoining the involved areas. Usually the cerebellum was completely spared. The spinal cord showed edema and congestion and a moderate degree of nerve damage but no perivascular or meningeal infiltration and no inflammatory exudate. Hence there was no myelitis in the strict sense of the word. However, this cord sparing may be accidental in a limited number of cases, and further study may show a true encephalomyelitis.

In the lungs, both gross and microscopic edema were invariably present. There was also a definite infiltration of the alveolar walls with polymorphonuclear and mononuclear cells, but no bacteria could be demonstrated. This indicates a definite early pneumonitis such as is frequently seen in virus diseases and raises a serious question as to the exclusive neurotropism of the virus. No inclusion bodies were found, but we no longer require them to diagnose a virus disease. The kidneys showed congestion and petechiae and, together with the heart and pancreas, terminal thrombi. In 1 case the thrombosis of a large sinus was associated with a subarachnoid hemorrhage.

These microscopic lesions differ from those of the St. Louis and Japanese Type B encephalitis by virtue of the massive early polymorphonuclear infiltration and the arteritis. Poliomyelitis does not show the massive brain involvement and distribution present here, nor does the disease under discussion show the anterior-horn-cell lesions that are characteristic of poliomyelitis. Encephalitis lethargica, a more chronic disease, shows chiefly a lymphocytic infiltration, with little diffuse brain involvement and meningeal reaction. There is none of the demyelination in this epidemic such as one sees in Schilder's disease and postpertussis and postmeasles encephalides. This epidemic is the most acute and violent encephalitis we have ever seen. In one of Dr Branch's cases there was massive destruction of a large amount of nervous tissue, severe cord lesions and widespread thrombosis of many vessels.

Dr Leo Alexander mentioned 4 cases seen at the Boston City Hospital. Postmortem examination was delayed too long to recover the virus in any case. He emphasized the high total protein with normal chlorides and sugar in the spinal fluid and the marked involvement of the mammillary bodies, paraventricular nuclei and the region about the third ventricle.

#### EASTERN HAMPDEN MEDICAL ASSOCIATION

The fifty ninth annual meeting of the Eastern Hampden Medical Association was held on Thursday, February 2, at the Oaks Hotel in Springfield.

The following officers were elected for 1939: president, Dr Michael J. Kranchuck, of South Hadley Falls, vice-president, Dr J. Joseph Klar, of Springfield, secretary-treasurer, Dr James J. Grace, of Springfield.

The retiring president, Dr T. H. McSweeney, delivered the annual discourse "Family Doctor or Federal Agent?"

The treasurer's report showed the society to be in better financial condition than for several years past.

Following the annual dinner served to the members, their wives and guests an elaborate entertainment was presented in the auditorium.

J. JOSEPH KLAR, M.D., *Secretary-Treasurer*

momentary twitching of his left arm three hours after supper—and was put to bed apparently normal. Next morning he was found in coma. He had a brief left-sided convulsion and despite sedation soon developed two more convulsions. The third convulsion lasted two and a half hours and was still in progress when the child arrived at the Children's Hospital, he was moribund and deeply cyanotic, and the right side was rigid, and the left side relaxed. Two cubic centimeters of intravenous luminal was required to stop the convulsions sufficiently to permit normal respiration. The first lumbar puncture forty-eight hours after onset, showed 246 cells, 45 per cent of which were polymorphonuclears, and the second, six hours later, showed 250 cells with 60 per cent polymorphonuclears. In this child the disease ran a mild and brief course. His temperature, 102°F on admission, promptly climbed to 105°F, where it remained for forty-eight hours, while the child was in coma and dependent on parenteral fluids. On the third day the temperature began to drop rapidly and by the fourth day was normal, where it remained. At the end of a week he was able to take feedings, though he remained paralyzed on his right side and showed severe inco-ordination of all movements on the left side. After three weeks with only slight improvement, an encephalogram was done which showed a questionable slight enlargement of the ventricles. At present the child still has a right hemiparesis and inco-ordination of movements on the left side.

All the cases were equally abrupt and violent in onset, and all the patients were as critically ill when they arrived at the hospital twenty-four to forty-eight hours after onset. Of the surviving cases, the second patient was in coma for three weeks and remains a pitiable wreck, with generalized spasticity. The third patient is in a cast because of a spastic hemiplegia and is almost completely deaf and apparently blind. One of the patients in the second group ran a temperature between 103 and 106°F for twenty-one days before he succumbed.

All the cases occurred during August and September and were of a violence comparable only to that of overwhelming sepsis or malignant poliomyelitis. All had two or three convulsions before coming to the hospital, and coma was universal. Vomiting, fever, cyanosis, rigidity and bulging fontanelles were almost universal. All had markedly increased intracranial pressure with cell counts ranging from 250 to 2000 cells, 45 to 100 per cent of which were polymorphonuclears. This preponderance of polymorphonuclear cells reversed itself within forty-eight to seventy-two hours so that 60 to 100 per cent were mononuclear cells after that time. Fever ranged between 103 and 107°F. Blood leukocytosis was always present, in some cases as high as 40,000 cells with 85 per cent polymorphonuclears. All the cases surviving beyond the first forty-eight hours developed a peculiar edema, with puffy face and limbs, which did not pit on pressure but was brawny and very slow to subside. (In the 2 instances in which the serum protein was determined, it was found to be well above the edema level.) All developed a considerable pallor due to secondary anemia.

For its violence of symptoms and critical course and for its universal outcome of death or hopelessly discouraging residual paralysis, this disease has been one of the most terrifying we have seen. The 5 patients who died showed pathologic changes consistent with equine encephalitis, and the virus was recovered from 3 cases—in 1 as late as seven days after onset.

Discussion brought out that because of the spinal fluid findings on admission which necessitated a differential diagnosis of poliomyelitis and septic meningitis, all cases

were treated with sulfanilamide until negative spinal-fluid cultures were obtained. Spinal fluid sugar and chloride determinations were essentially normal. In no case were red-blood cells found in spinal fluid during the early stages.

Dr LeRoy D Fothergill reported on the isolation and identification of the virus. While equine encephalitis due to a virus has been known in Europe for a long time, interest in the disease in this country was first aroused by an epidemic among horses in the San Joaquin Valley in California during 1930-1931. Prompt study isolated the virus and proved its etiologic role. The next problem was the mode of transmission. It was first demonstrated that sick and well animals could be kept together without spread of the disease. In 1933 it was shown that the disease could be transmitted from one animal to another by a mosquito—*Aedes aegypti*. Later, eight varieties of the *Aedes* were found capable of transmitting the disease. Next it was shown that the virus could be recovered from the blood stream of the horse for only a few hours after the onset of the illness and before the temperature rose

—thus making the period available for a potentially infective mosquito meal very short. Furthermore it was found that the mosquito could not transmit the disease until four to six days after the blood meal. The reason for this latent period is not known. Once infected the mosquito probably harbors the virus the rest of its life, but it does not transmit the virus to other mosquitoes or its offspring. Later the tick, *Dermacentor andersoni* was found capable of transmitting the disease, of harboring the virus for a long time and of passing it on to offspring in the eggs. The first epidemic in the East broke out simultaneously in the coastal salt marshes on both sides of Chesapeake Bay. A study of this outbreak demonstrated a virus but one which is immunologically distinct from the virus of the disease in the West. The equine disease caused by the Eastern variety is also characterized by a much more severe course and a mortality rate as high as 90 per cent, in comparison with the 25 per cent mortality of the Western type of disease.

In the present epidemic among human beings, the virus was recovered by injecting a suspension of fresh brain intracerebrally into a mouse. After twenty-four hours the mouse stops eating, its fur becomes rough, and it later develops convulsions which result in death in forty-eight to seventy-two hours. The virus can be recovered from the animal's brain and passed on indefinitely. In this way the virus has been recovered from 8 human cases. As yet it has not been recovered from the blood or spinal fluid. The virus was further identified by protection tests, where in three animals—a normal mouse, a Western-type immune and an Eastern type immune—were injected, only the last mouse survived.

Next came the problem of proving the etiology of the disease in those cases which recovered and that of investigating the possibility of sub-clinical infections, of mild unrecognized cases leaving no residual paralysis and of family contacts. The last is unlikely, because people working with the virus for several years have not developed antibodies. Virus-neutralization tests were used for this study. The results so far have shown that the serums from veterinary and family contacts have no neutralizing power, while that from one of the convalescent cases at the Children's Hospital was able to neutralize 100,000 lethal doses.

Discussion brought out that the virus cannot be recovered from the brain of a case in which death is prolonged. Work is being done to discover how early the neutralization test becomes positive. In addition, Dr Roy F Feemster of the Massachusetts Department of Public Health is

titrating various parts of the brain to see if the virus has any tendency to localize in special areas.

Dr John Dingle reported on some of the newer epidemiologic features. While adult man is apparently not susceptible to the disease, the mouse, guinea pig, cat, dog, horse and sheep are. For this reason the disease is ideal for laboratory investigations. Some animals can acquire the disease by subcutaneous injection or even feeding of the virus. Soon this was extended to show that most of the common birds, with the exception of the chicken, are susceptible, among them the pigeon. During the past summer, pigeon breeders all along the Atlantic seaboard noticed an unusual number of deaths for no apparent reason. One of these pigeons was studied, and its brain was shown to contain the Eastern strain of equine encephalitis virus. The pigeon deaths all ceased abruptly with the onset of cold weather and coincidental with the end of the equine epidemic. This raises the question of the role of the pigeon as a reservoir or secondary host and may be the explanation of the simultaneous outbreak on both sides of twenty five-mile wide Chesapeake Bay.

Discussion brought out that the present epidemic in Massachusetts and northern Rhode Island involved some 200 horses, that the virus from human cases has been passed on in both pigeons and horses, and that calves get only a mild temperature reaction and no severe illness when inoculated, though an encephalitis of cattle is known in Europe and is due to a different virus. The incubation period after inoculation in the human being is unknown but judging from animal experiments is probably between two and five days. The major missing link in the tale, so far, is failure to find mosquitoes or ticks which harbor the virus. But the circumstantial evidence of no contact cases, seasonal incidence and cases separated by several miles is strong, and the statistical probability of finding such insects in the field very slight. Where the disease is harbored during the winter, the natural reservoir and possibility of other intermediate hosts and the possibility of carriers constitute the important unsolved problems.

Dr Sidney Farber presented the pathologic findings and pointed out that much of his work was excellently supplemented and confirmed by that of Dr Charles F. Branch. Grossly the brains showed nothing distinctive aside from considerable edema, with an increase in weight, and an intense congestion most striking in the pons, medulla and basal ganglia. All 5 cases showed a pressure cone.

Microscopically there were four outstanding features (1) Nerve cells throughout the brain showed Nissl substance breakdown, chromatolysis and general cellular dissolution, particularly in the pons, medulla and basal ganglia. J. JOSEPH KLAR, M.D., *Secretary-Treasurer*

## NOTICES

### REMOVAL

HENRY M BAKER, M D, announces the removal of his office to 353 Commonwealth Avenue, Boston.

### HOSPITAL RESEARCH COUNCIL

The Hospital Research Council will hold a meeting in the Ether Dome of the Massachusetts General Hospital on Tuesday, February 28, at 5 00 p m The program will be as follows

#### STUDIES PERTAINING TO THE PHYSIOLOGY OF NORMAL JOINTS

The Origin and Nature of Normal Synovial Fluid  
Dr Marian W Ropes

The Removal of Proteins and Aqueous Solutions from Normal Joints Dr Walter Bauer

The Passage of Proteins and Pneumococci from the Vascular System into Joints Dr Granville A Bennett.

The Relation of These Studies to the Metabolism of Cartilage. Dr Eric G L Bywaters

HENRY K. BEECHER, M D, *Secretary*

### SALEM HOSPITAL CONFERENCES

There will be conferences at the Salem Hospital every Friday morning at 9 00 until further notice. Physicians are cordially invited to attend

The form of the conferences for each month will be as follows

- First Friday — Grand ward rounds
- Second " — Clinicopathological conference
- Third " — Grand ward rounds
- Fourth " — Clinical conference.

If there is a fifth Friday in any month, there will be either grand ward rounds or a tumor-clinic teaching conference

### SOUTH END MEDICAL CLUB

The next meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, February 21, at 12 o'clock noon.

Dr Howard F Root will speak on "Hypertension and Its Complications"

Physicians are cordially invited to attend.

JOHN B HALL, M D, *Secretary*

### CARNEY HOSPITAL

The monthly clinical meeting and luncheon of the Carney Hospital will be held in the Andrew Carney Assembly Room on Monday, February 20, at 11 30 a m

#### PROGRAM

##### Case reports

Infections of the Foot Usual anatomical locations and treatment. Dr John G Arent Discussion by Drs Archibald McK Fraser, John L Doherty and John J Todd.

Physicians and medical students are cordially invited to attend

ROY J HEFFERNAN, M D, *Secretary*

### MASSACHUSETTS ITALIAN MEDICAL SOCIETY

The regular monthly meeting of the Massachusetts Italian Medical Society will be held at the Hotel Kenmore, Boston, on Friday evening, February 24, at 9 00

#### PROGRAM

Pathology of Peptic Ulcer Dr Marino F Vidoli  
Sociomedical Problems in Italy Marquis Carlo De Constantin de Chateauneuf, Italian Consul General of New England

A general discussion will follow The medical and allied professions are cordially invited to attend.

CARL F MARALDI, M D, *Secretary*

### CAMBRIDGE HOSPITAL

The regular clinicopathological meeting of the staff of the Cambridge Hospital will be held at the hospital, 330 Mt Auburn Street, Cambridge, on Tuesday, February 21, at 8 30 p m.

Dr Elliott C Cutler will speak on "Surgical Treatment of Peptic Ulcer"

All members of the medical profession are cordially invited to attend

STEPHEN M BIDDLE, M D, *Secretary*

### NORFOLK DISTRICT MEDICAL SOCIETY

The regular meeting of the Norfolk District Medical Society will be held in the Hotel Somerset, Boston, Tuesday evening, February 28, at 8 30 Tel KEN 2700

#### PROGRAM

The Huntington Hospital and the Cancer Problem.  
Dr Joseph C Aub

Kodachrome Views of Contagious Disease. Dr Edwin H Place

Collation.

FRANK S CRUICKSHANK, M D, *Secretary*

### MEDICAL CLINIC AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 p m on Thursday, February 23, in the amphitheater of the Peter Bent Brigham Hospital, Dr Marshall N Fulton, associate in medicine, Harvard Medical School, and physician, Peter Bent Brigham Hospital, will give a medical clinic. Practitioners and medical students are cordially invited to attend

### BOSTON MEDICAL HISTORY CLUB

The Boston Medical History Club will meet at the Boston Medical Library, 8 Fenway, Boston, on Monday evening, February 20, at 8 15

Dr Leroy M S Miner will talk on "The Development of Our Knowledge of the Diseases of the Teeth"

Members of the medical profession and other interested persons are cordially invited to attend

PAUL D WHITE, M D, *President*

BENJAMIN SPECTOR, M D, *Secretary*

## SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING  
MONDAY, FEBRUARY 20

## MONDAY FEBRUARY 20

- \*11.30 a. m. Carney Hospital Monthly clinical meeting and luncheon.
- \*8.15 p. m. Boston Medical History Club Boston Medical Library 3 Fenway

## TUESDAY FEBRUARY 21

- 9-10 a. m. Joseph H Pratt Diagnostic Hospital Allergy Clinic with Case Presentation Dr E A Brown.
- \*10 a. m. 12.30 p. m. Tumor clinic Boston Dispensary
- \*12 m. South End Medical Club Headquarters of the Boston Tuberculosis Association 554 Columbus Avenue, Boston
- \*8.30 p. m. Cambridge Hospital Clinicopathological meeting of staff

## THURSDAY FEBRUARY 23

- 8.30-9.30 a. m. Exchange visit Surgical and Orthopedic Staffs of the Peter Bent Brigham and Children's hospitals, held this week at the Children's Hospital Orthopedic.
- \*9-10 a. m. Joseph H Pratt Diagnostic Hospital Medical Social Service case presentation District Service and Social Service staffs
- \*3.30 p. m. Medical clinic at the Peter Bent Brigham Hospital

## FRIDAY FEBRUARY 24

- \*9.10 a. m. Joseph H Pratt Diagnostic Hospital. The Present Status of Specific Therapy for Pneumonia Dr Maxwell Finland
- \*10 a. m. 12.30 p. m. Tumor clinic. Boston Dispensary
- \*9 p. m. Massachusetts Italian Medical Society Hotel Kenmore, Boston

## SATURDAY FEBRUARY 25

- 9.10 a. m. Joseph H Pratt Diagnostic Hospital Hospital case presentation Dr S J Thannhauser
- \*10 a. m. 12 m. Staff rounds of the Peter Bent Brigham Hospital Conducted by Dr Henry A. Christian

## SUNDAY FEBRUARY 26

- 4 p. m. Illustrated, public, health lecture, Faulkner Hospital auditorium Tuberculosis in this Community Dr David Halberstam.
- 4 p. m. Free public lecture Harvard Medical School Amphitheater of Building D Nervous Breakdowns. Dr Vernon P. Williams.

\*Open to the medical profession

for criticism, for most of the opinions of the author will be endorsed by well informed physicians. Interspersed in the text the reader will find humor and sarcasm, which tend to emphasize the arguments advanced. Although the book is written especially for the non-medical person there is enough of science to interest those physicians who have not given much attention to this subject. Doctors may recommend this book to their patients with propriety. The only objection to it will come from quacks and manufacturers of proprietary drugs.

*The Physiology of Anesthesia.* Henry K. Beecher 398 pp London, New York and Toronto Oxford University Press, 1938 \$3 75

Dr Beecher approaches the subject as an expert clinical anesthetist, as a teacher of anesthesia and especially as one who has made a thorough study of the physiological basis of the problem in all its varied aspects.

The book begins with a study of the primary effects of anesthesia, namely the effects on the nervous system as a whole. Herein are considered the meaning of anesthesia and narcosis and the various theories of anesthetic action. Next is the section on respiration, in which the chemistry of gaseous exchange, the behavior of the respiratory center, the viscosity of air and the related problems of obstruction of the airway are considered. Next is the section on circulation, in which the effects of various anesthetics on the heart and on other elements in the vascular system are treated. The final chapter deals with "Organic Effects of Anesthetic Agents." This includes a discussion of blood changes—those in the cells, physical properties and blood chemistry—and a consideration of the effects of anesthetics on the liver and other vital organs and finally on metabolic rate and temperature.

This scholarly work should serve a variety of useful purposes. It should be of great value to the medical student learning the foundations of this important subject. It should serve the professional anesthetist, providing timely warnings of the hazards involved in the use of certain anesthetics or in the use of any anesthetics without critical appraisal of danger signs. It should serve the surgeon in like manner, for he, as well as the anesthetist, should understand fully what is involved in the problem which he shares with the anesthetist. If it were not already obvious, this book should furnish convincing evidence of the importance of teamwork between surgeon and anesthetist. The book is also full of significant material for the physiologist. In the discussion of the relation between the chemical properties of the anesthetics and their action on nervous tissue, and in the related consideration of the theories of anesthesia, there are many important clues which may ultimately lead to a better understanding of the nervous system.

*Spinal Anesthesia* Louis H. Maxson. 409 pp Philadelphia, London, New York and Montreal J B Lippincott Co, 1938 \$6.50

This is a very valuable monograph on a most important aid to safe and successful surgery. The writer discusses in detail the development of spinal anesthesia from its earliest days, in its physiological, pharmacological and technical aspects. His own methods of choice are described extensively, with the reasons therefor. Constant comparisons of the ideas and methods of others of authority in this field are made. An excellent bibliography is appended.

## BOOK REVIEWS

*Our Common Ailment. Constipation Its cause and cure* Harold Aaron 192 pp New York Dodge Publishing Co, 1938 \$1.50

It is probably true that informed persons agree with the writer of this book that 10 per cent of the people are more or less constipated and that in a large proportion of these cases the ailment is a functional rather than an organic disease, which may be corrected under intelligent and persistent management. It is, however, too often found that people who should strive for normal behavior of the bowels are impatient and seek relief by taking drugs which tend to establish chronicity. However that may be, Dr Aaron believes that a proper understanding of the causes and treatment of this trouble will be appreciated by those who really want to secure a return to normal conditions. With this in view he expects that many people will be led to profit by his advice.

In order to enable the patient to prevent and cure bad bowel habits the author first gives a description of the anatomy and physiology of the digestive organs. He then discusses the factors that must be considered in order to differentiate organic and functional disease for if the former is confused with the latter dire results are liable to follow. Emphasis on prevention is stressed. This depends in large measure on the recognition of parental responsibility with respect to the education of the child. Adequate space is given to the futility and danger of self-medication, and the approved methods to be employed in bringing about restoration of normal habits are set forth with warnings against harmful drugs and the employment of quacks. Instructive chapters deal with hemorrhoids and colitis.

The book is well written, and there is little opportunity

## EXPERIENCES WITH GASTRECTOMY, TOTAL AND SUBTOTAL\*

FRANK H. LAHEY, M.D.†

BOSTON

THE following report is presented in the light of certain recent changes in the attitude toward total and subtotal gastrectomy. In the first place, there is more universal acceptance of the belief that gastroenterostomy is not an operation to be routinely applied in the surgical treatment of peptic ulcer. Secondly, it is more generally agreed that subtotal gastrectomy is followed by lower values of gastric acidity, fewer recurrent ulcers, and a better digestive state than results from other less radical surgical procedures. Thirdly, it has been demonstrated by numerous surgeons that patients with seemingly hopeless carcinoma or sarcoma of the stomach can be submitted to total gastrectomy with prolongation of life and possible cure. These things being so, it will be of interest to review some of the experiences we have had and some of the deductions we have drawn in handling 362 cases of subtotal and 9 cases of total gastrectomy. Of the 362 subtotal gastrectomies which we have done, 162 were for cancer and 200 for ulcer.

Up to the present time we have treated in the clinic, under bed management, 3534 patients with ulcer—249 with gastric and 3285 with duodenal ulcers, included in this number have been 115 patients with gastrojejunal ulcers. In order that our attitude toward the surgical treatment of peptic ulcer may be clear, we wish to state that of this entire series only 8 per cent of the patients with duodenal ulcer and but 23 per cent of those with gastric ulcer were submitted to surgery.

The indications for surgery of peptic ulcer, which remain quite unchanged from year to year, are briefly as follows: failure to relieve pain under medical management, perforation, hemorrhage, obstruction and the suggestion of possible malignant degeneration superimposed on a gastric ulcer. We and others have written so much on the question

of indications for surgery in cases of peptic ulcer that further discussion of the subject is unnecessary here.

Since we have had occasion to perform subtotal and total gastrectomies in a large series of cases, and since this experience has involved a variety of types of anesthesia and a variety of types of surgical procedure, it seems particularly worthwhile to present some of the deductions drawn from this experience and some of the modifications of the various anesthetic and surgical procedures, and to state the reason why the latter have been made. As I have repeatedly stated, there has been no operative procedure with which we have dealt which has been more difficult to standardize successfully, and in which it has been harder to eliminate complications and reduce the mortality, than that of total and subtotal gastrectomy.

The mortality in these radical operations for cancer of the stomach will always be high, owing to the fact that many patients are in advanced years with other associated serious lesions, that they often present themselves late in the disease, and particularly that since there is no other possible form of treatment the acceptance of desperate risks is entirely justifiable.

It is quite a different problem, however, when we consider the question of subtotal gastrectomy for gastric, duodenal or gastrojejunal ulcer. Here there does not exist the justification for unusual risks, and here one cannot justifiably continue to perform these operations if the mortality remains high. It is because we have successfully and progressively diminished the mortality of subtotal gastrectomy for ulcer that I am prompted to discuss some of our experiences. Our mortality with this operation three and a half years ago was 18 per cent. In the following year it was 11 per cent, and for the past year and a half it has been zero. We have now performed 47 consecutive subtotal gastrectomies for ulcer without a death. Included in this series are 9 cases of gastrojejunal ulcer, in

Presented at the annual meeting of the New England Surgical Society, Boston, October 1, 1938. From the Department of Surgery, Lahey Clinic, Boston.

\*Director, Lahey Clinic.

which the jejunum with its contained ulcer was resected together with the stomach, and 1 case of gastrojejunocolic fistula, in which the stomach, jejunum and the entire ascending and transverse colon were resected in one block.
